

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

#### Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

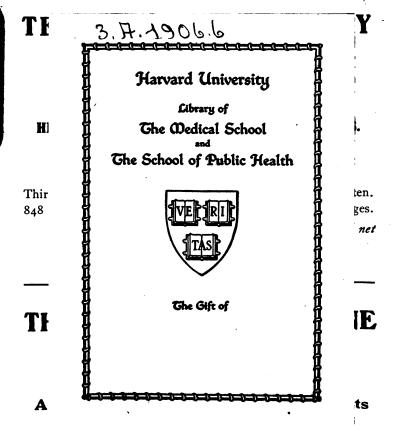

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + Refrain from automated querying Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

#### **About Google Book Search**

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at http://books.google.com/

# Gould's Medical Per Dictionaries.

The Standard Medical Reference Books.

198,000 HAVE BEEN SOLD.

BY GEORGE M. GOULD, A.M., M.D., Editor of American Medicine.

THE ILLUSTRATED DICTIONARY OF MEDICINE, BIOLOGY, AND ALLIED SCIENCES. INCLUDING THE PRONUNCIATION, ACCENTUATION, DERIVATION, AND DEFINITION OF THE
TERMS USED IN MEDICINE AND THOSE SCIENCES COLLATERAL TO IT:
BIOLOGY (ZOOLOGY AND BOTANY), CHEMISTRY, DENTISTRY, PHARMACOLOGY, MICROSCOPY, ETC. With many Useful Tables and numerous
Fine Illustrations. Large Square Octavo. 1633 pages. Fifth Edition
now ready. Full Sheep, or Half Dark-Green Leather, net, \$10.00;
With Thumb Index, net, \$11.00; Half Russia, Thumb Index, net, \$12.00

A DICTIONARY OF NEW MEDICAL TERMS. Being a Supplement to "Gould's Illustrated Dictionary," consisting of 571 double-column pages, containing upwards of 38,000 words, uniform in size and type with the "Illustrated" and containing many thousand new terms and new definitions. Large Square Octavo.

Full Sheep or Half Dark Green Leather, \$5.00; with Thumb Index, \$6.00

Half Russia, Thumb Index, \$7.00

THE STUDENT'S MEDICAL DICTIONARY. INCLUDING ALL THE WORDS AND PHRASES GENERALLY USED IN MEDICINE, WITH THEIR PROPER PRONUNCIATION AND DEFINITIONS, BASED ON RECENT MEDICAL LITERATURE. With Tables of the Bacilli, Micrococci, Leukomains, Ptomains, etc., of the Arteries, Muscles, Nerves, Ganglia, and Plexuses; Mineral Springs of the U. S., etc. Eleventh Edition, Illustrated. Revised, Enlarged by over 150 pages. Small Square Octavo. Half Dark Leather, net, \$2.50; with Thumb Index, net, \$3.00

THE POCKET PRONOUNCING MEDICAL LEXICON. 30,000 words pronounced and defined. Containing all the Words, their Definition and Pronunciation that the Student generally comes in contact with; also elaborate Tables of the Arteries, Muscles, Nerves, Bacilli, etc., etc.; a Dose List in both English and Metric Systems, etc., arranged in a most convenient form for reference and memorizing. Fourth Edition, 837 pages. 64mo.

Full Limp Leather, Gilt Edges, net, \$1.00; Thumb Index, net, \$1.25

# COMPEND OF ANATOMY

POTTER

#### From The Southern Clinic.

"We know of no series of books issued by any house that so fully meets our approval as these ? Quiz-Compends?. They are well arranged, full, and concise, and are really the best line of text-books that could be found for either student or practitioner."

### BLAKISTON'S ?QUIZ-COMPENDS?

#### The Best Series of Manuals for the Use of Students.

Price of each, Cloth, \$1.00 net. Interleaved, for taking Notes, \$1.25 net.

These Compends are based on the most popular text-books and the lectures of prominent professors, and are kept constantly revised, so that they may thoroughly represent the present state of the subjects upon which they treat.

\*\*The authors have had large experience as Quiz-Masters and attachés of colleges,

and are well acquainted with the wants of students.

They are arranged in the most approved form, thorough and concise, containing

over 900 fine illustrations, inserted wherever they could be used to advantage.

Can be used by students of any college. They contain over 900 Illustrations.

They contain information nowhere else collected in such a condensed, practical

#### shape. Illustrated Circular Free.

POTTER'S ANATOMY. Seventh Revised and Enlarged Edition. Including Visceral Anatomy. Can be used with either Morris' or Gray's Anatomy. 138 Illustrations and 16 Plates of Nerves and Arteries, with Explanatory Tables, etc.

BRUBAKER. PHYSIOLOGY. Eleventh Edition, with new Illustrations and a Table of Physiological Constants. Enlarged and Revised.

LANDIS. OBSTETRICS. Eighth Edition. Revised and Edited by WM. H. Wells, M.D., Instructor Jefferson Medical College, Philadelphia. 56 Illustrations.

POTTER. MATERIA MEDICA, THERAPEUTICS AND PRESCRIPTION WRITING. Seventh Revised Edition.

WELLS. GYNECOLOGY. Third Edition. With 145 Illustrations.

GOULD and PYLE. DISEASES OF THE EYE AND REFRACTION. Including Treatment and Operations and a Section on Local Therapeutics. With Formulæ and 100 Illustrations, several of which are in Colors. Third Edition.

HORWITZ'S SURGERY, Minor Surgery, and Bandaging. Fifth Edition, Enlarged and Improved. With 98 Formulæ and 167 Illustrations.

LEFFMANN. CHEMISTRY, Inorganic and Organic. Fifth Edition. Including Urinalysis, Animal Chemistry, Chemistry of Milk, Blood, Tissues, the Secretions, etc.

STEWART. PHARMACY. Sixth Edition. Based upon Prof. Remington's Text-Book of Pharmacy.

BALLOU. VETERINARY ANATOMY AND PHYSIOLOGY. With 29 graphic Illustrations.

WARREN. DENTAL PATHOLOGY AND DENTAL MEDICINE. Fourth Edition, Illustrated. Containing all the most noteworthy points of interest to the Edition, Illustrated. Containing all the most Dental Student, and a Section on Emergencies.

HATFIELD. DISEASES OF CHILDREN. Colored Plate. Third Edition, Revised and Enlarged.

ST. CLAIR. MEDICAL LATIN. Second Edition.

SCHAMBERG. DISEASES OF THE SKIN. Fourth Edition, Revised and Enlarged. More than 100 Illustrations.

RADASCH. HISTOLOGY. With 08 Illustrations.

THAYER. SPECIAL PATHOLOGY. With 34 Illustrations.

KYLE. EAR, NOSE, AND THROAT. 85 Illustrations.

HIRSCH. GENITO-URINARY AND VENEREAL DISEASES, AND SYPHILIS. Illustrated.

PITTFIELD. BACTERIOLOGY. Illustrated.

#### TO THE MEMORY

OF

AN AMERICAN SURGEON AND ANATOMIST,
WILLIAM H. PANCOAST,

FORMERLY PROFESSOR OF ANATOMY IN JEFFERSON MEDICAL COLLEGE,
THIS COMPEND OF HUMAN ANATOMY

15

AFFECTIONATELY DEDICATED.

#### PREFACE TO THE SEVENTH EDITION.

The twenty years which have elapsed since this compend was first issued have brought many changes of nomenclature and description into the teaching of Anatomy. The present edition has been entirely re-written and brought into harmony with the latest text-books on this subject. The text has been expanded wherever greater detail seemed desirable, but in so doing the condensed form of statement heretofore adopted has been care-The total number of illustrations has been infully followed. creased from 117 to 138, and many of the cuts used in former editions have been replaced by newer ones. The Tables and Plates, heretofore published in an appendix, have been thoroughly revised, and are now placed in their natural positions in These changes have increased the size of the volume by 82 pages, and have made it practically a new book, which the author hopes will receive a continuance of the favor heretofore extended to the previous editions.

Originally designed for the use of the medical student in preparing for the exercises of the quiz-room and for his examinations, the text is confined to the essentials of each structure treated of, which are arranged in such a manner as to facilitate their rapid acquirement. All superfluities of description have been studiously avoided, and only such matter inserted as should be thoroughly known in order to pass a rigid examination on any organ or structure of the human body. The descriptions will be found to closely follow Gray, though Morris, Quain, and other recognized authorities have been freely consulted during the preparation of the text. For many of the special arrangements the author is indebted to the lectures of Professor W. H. Pancoast, formerly of Jefferson Medical College, and to the quizzes of Dr. Henry Morris, at one time assistant to the chair of Anatomy in the same school.

While striving to carry out the object of this series in furnishing the medical student with a condensed manual of Anatomy, the author has endeavored, from a strong appreciation of the importance of the subject, to make this volume deserving of first rank among its kind; and believing that a judicious condensation, which does not slight the essential features of the subjects treated, cannot fail to be of benefit in any department of science, he again commits this compend to the teachers and students of Anatomy, in the hope that it may continue to be found worthy of a place alongside the more exhaustive and exhausting textbooks.

SAM'L O. L. POTTER.

San Francisco, 1903.

#### EXPLANATION.

Figures or letters in parentheses, thus—(14), (a), refer to the same figures or letters on the adjoining illustration; except in the Tables of Arteries, in which figures in parentheses serve as cross-references to other divisions of the tables.

# A COMPEND OF HUMAN ANATOMY.

Define the term Anatomy. Derived from the Greek ἀνα, through, and τέμνειν, to cut, it strictly means dissection, but 's technically applied to that science which treats of the structure of organized bodies.

Name the divisions of Descriptive Human Anatomy. They are,—Osteology, the anatomy of the bones; Syndesmology, of the joints; Myology, of the muscles; Angiology, of the vessels; Neurology, of the nerves; Splanch-nology, of the internal viscera; Adenology, of the glands; Dermatology, of the skin; Genesiology, of the generative organs.

#### OSTEOLOGY.

State the number of Bones in the Adult Human Skeleton. It is variously stated by different anatomists. Excluding the teeth (which belong to the tegumentary system), the Wormian and the sesamoid bones, the number is 206. Excluding also the 6 ossicles of the middle ear the whole number would be 200. Leaving out also the 2 patellæ and the hyoid bone, the number in the skeleton proper would be 197 bones. Of these, the vertebral column contains 26, the cranium 8, the face 14, the walls of the thorax (sternum and ribs) 25, the upper extremities 64, and the lower extremities 60. They are divisible into four classes,—the long, short, flat and irregular bones.

Long Bones number 90, act as supports, or levers, and are known by having a medullary canal in the centre of each, a shaft (diaphysis), and two extremities. They are developed by osseous deposit in cartilage, and include the clavicle, humerus, radius, ulna, femur, tibia, fibula, metacarpal and metatarsal bones, and the phalanges.

Short Bones number 30, and are found where strength is required, but

limited motion. They also are developed by osseous deposit in cartilage and include the bones of the carpus and tarsus, the former having 16 and the latter 14.

Flat Bones number 38, protect the viscera by forming walls around them, and afford extensive attachment for muscles. They are developed by osseous deposit in membranes, and consist of 2 dense layers, separated by a cellular or cancellous osseous tissue, the diplož. They include the occipital, parietal and frontal (bones of the cranium); the nasal, lachrymal and vomer (bones of the face); the scapula, os innominatum, sternum and ribs.

Irregular Bones are 39 in number, and include the vertebræ, sacrum, coccyx, the temporal, ethmoid, and sphenoid bones, and the bones of the face, except the nasal, lachrymal, and vomer.

#### Bones of the Head number 22, and comprise the-

Cranial Bones 8,—the frontal, 2 parietal, occipital, 2 temporal, the sphenoid and the ethmoid bones.

Facial Bones 14,—2 superior maxillary, 2 malar, 2 nasal, 2 lachrymal, 2 palate, 2 inferior turbinated, vomer and inferior maxillary.

#### Bones of the Trunk number 53, as follows, viz.—

Vertebræ 24,-7 cervical, 12 dorsal, and 5 lumbar vertebræ.

Thorax 25,—7 pairs of true ribs, 3 pairs of false ribs, 2 pairs of floating ribs (articulating with the bodies of the dorsal vertebræ), and the sternum.

Pelvis 4,—the sacrum, the coccyx, and 2 ossa innominata; each os innominatum consisting of 3,—the ilium, ischium, and pubes.

#### Bones of each Upper Extremity number 32, as follows:—

Shoulder 2,—the clavicle and scapula.

Arm 1,-the humerus.

Forearm 2,-the radius and ulna.

Hand 27,—8 carpal bones,—the scaphoid, semilunar, cuneiform, pisiform, trapezium, trapezoid, os magnum, and unciform,—5 metacarpal, and 14 phalanges.

#### Bones of each Lower Extremity number 29, viz.—

Thigh 1,—the femur.

Leg 2,—the tibia and fibula.

Foot 26,—7 tarsal bones,—the astragalus, os calcis, scaphoid, cuboid, external, middle and internal cuneiform,—5 metatarsal, 14 phalanges.

#### Unclassified Bones are the-

Patellæ 2, which are sesamoid bones, each developed in the tendon of the quadriceps extensor femoris muscle.

Hyoid Bone 1,—the tongue-bone, not articulated to the skeleton.

Malleus, Incus, Stapes (3 pairs)—the bones of the middle ear.

Sesamoid Bones, of variable number, situated in the tendons of the gastrocnemius and peroneus longus muscles, and in the flexor tendons of the great toe and the thumb.

Wormian Bones (ossa triqueta), sometimes found in the cranial sutures, are not constant in number or size.

Principal Eminences on Bones. Heads, are convex and smooth, for articulation in movable joints. Condyles, are irregularly-shaped heads. Trochanters, when for turning the bone. Tuberosities, are broad, uneven prominences. Tubercles, are small tuberosities. Spines, or Spinous processes, when sharp and slender. A pophysis (an excrescence), is a process or marked bony prominence which has never been separate from the bone. Epiphysis (an accretion), is a process which was developed separately and afterward became united to the bone by ossification of the intermediate tissue.

Other Names given to Bony Prominences. There are several adjectives applied to them from their fancied resemblances, such as—Azygos, without a fellow; Clinoid, like a bed; Coracoid, like a crow's beak; Coronoid, hooked like a crow's beak; Hamular, hook-like; Malleolar, like a mallet; Mastoid, like a nipple; Odontoid, tooth-like; Pterygoid, wing-like; Rostrum, a beak; Spinous, thorn-like; Styloid, pen-like; Squamous, scaly; Vaginal, ensheathing, etc.

Cavities of Bones. Articular cavities are called *Cotyloid*, cup-like; *Glenoid*, shallow; *Trochlear*, pulley-like; *Facet*, if smooth; *Alveolar*, or *Alveoli*, when socket-like. Non-articular cavities are named fossæ, sinuses, aqueducts, foramina, canals, fissures, notches, cells, grooves, depressions, etc.

Composition of Bone. Organic or animal matter, about  $\frac{1}{3}$ , consisting of gelatin, vessels and fat. Inorganic, or mineral, about  $\frac{2}{3}$ , consisting of phosphate and carbonate of calcium (62 $\frac{1}{3}$  per cent.), with fluoride of calcium, phosphates of magnesium, sodium, and chloride of sodium (4 $\frac{1}{3}$  per cent.). Heat will remove the organic matter and leave the inorganic; dilute Nitric or Hydrochloric acid will remove the inorganic, and leave the organic. In old age the inorganic constituents predominate, and the bones are brittle; in youth the organic predominate, and epiphyseal dislocation is more common than fracture, especially in the long bones of the extremities.

Structure of Bone. Bone is composed of an outer compact layer, and an inner cellular or spongy structure. It is surrounded, except at the articular cartilages, by a vascular fibrous membrane, the Periosteum, which receives the insertions of all tendons, ligaments, etc.; and the central cavity

of long bones is lined by a similar structure, the *Endosteum*. The transverse section of bone, examined microscopically, shows—

Haversian Canals,—diameter  $\frac{1}{500}$  inch, for the passage of vessels.

Canaliculi,—diameter 18000 inch, radiating from the canals, and connecting them with the lacunæ.

Lacuna,—arranged circularly around the canals, and contain the bonecells, appearing as irregular dark spaces.

Haversian Spaces,—connect the canals with the medullary spaces, and divide one Haversian system from another. An Haversian System comprises an Haversian canal with its lamellæ, lacunæ, and canaliculi.

Concentric Lamella,—of bone tissue, around the canals.

Circumferential Lamellæ,—are bone layers binding the canals together.

Interstitial Lamella,—woven in between the concentric lamella.

What is the Marrow of Bone? In young bones it is a tenacious, transparent fluid, free from fat. In adult bones it is of a yellow color, and consists of fat in varying proportion and extractive matters. It is found in the medullary canal, the cancellous texture, and the large Haversian spaces.

What Vessels are found in Bones? Arteries, veins, and some say lymphatics. The Arteries are,—the nutrient, entering at the nutrient foramen; the articular, nourishing the cancellous structure; and the periosteal, which supply the periosteum and the compact structure. The Veins emerge from the ends, the shaft, and from the nutrient foramen.

Describe the process of Ossification. The site of bone is first occupied by a mucoid substance, which becomes temporary cartilage (blastema) in the second month of fœtal life. The young bone-cells (osteo-blasts) are then deposited in the cartilage at certain points, and their deposition and subsequent pressure cause the absorption of the cartilage. In most of the bones of the head and face, ossification is intra-membranous instead of intra-cartilaginous. The first bones in which ossification appears are the clavicle and inferior maxillary (5th to 7th fœtal week); the last is the pisiform bone (12th year). Epiphyses ossify after birth and begin uniting to the bone from the age of put berty, and in the inverse order to that in which their ossification began, excepthe lower end of the fibula, which ossifies and is joined to the shaft earlier than its upper end.

#### THE BONES OF THE TRUNK.

#### THE VERTEBRAL COLUMN.

Characteristics common to the Vertebræ. Each of the 24 spinal vertebræ consists of a body and an arch, the latter being formed by 2 pedicles and 2 laminæ, which support 7 processes. The—

 $\dot{\text{Digitized by}} \, Google$ 

Body,—is thick and spongy, convex in front (1) from side to side, concave vertically, and on the upper and lower surfaces, which are surrounded by a bony rim. Anteriorly are small *joramina* for nutrient vessels, posteriorly a large *joramen* for the exit of the venæ basis vertebrarum.

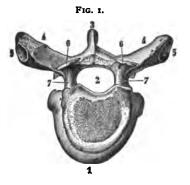

Pedicles (7),—project backward from the body, inclining outwardly. They are notched above and below, thus forming, with the adjacent notches, the *Intervertebral Foramina* for the entrance of vessels and the exit of the spinal nerves.

Lamina,—are 2 broad plates, meeting in the spinous process behind, and

rough on their upper and lower borders for the attachment of the ligamentum subflava.

Transverse Processes (4),—one on each side projecting outward; those of the first ten dorsal vertebræ have articular facets (5) for the tubercles of the ribs.

Articular Processes (6),—two on each side, superior (6) and inferior, project from the junction of the laminæ and pedicles, and articulate above and below with the articular processes of the adjacent vertebræ. Their superior

facets look upward in the cervical region, outward in the dorsal, and inward in the lumbar.

Spinous Process (3),—projects backward from the junction of the laminæ with each other, sometimes very obliquely.

Spinal Foramen (2),—is the space enclosed by the body, pedicles and laminæ, and which, when the vertebræ are articulated, forms part of the spinal canal.

The Spinal Vertebræ are distinguished as cervical 7, dorsal 12, and lumbar 5. Each of these divisions has several peculiar features, but their especial characteristics are as follows:—

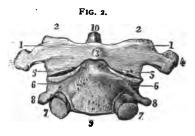

Cervical Vertebra—are pierced at the bases of their transverse processes by the vertebral foramina, which transmit the vertebral artery, vein, and plexus.

Dorsal Vertebra—have facets and demifacets on their bodies, for articulation with the heads of the ribs.

Lumbar Vertebræ—are marked by the absence of the foramina and facets which distinguish the other two classes.

Peculiar Vertebræ are 9 in number,—the Atlas or 1st cervical, the Axis or 2d cervical, the Vertebra Prominens, or 7th cervical, the 1st, 9th, 1oth, 11th, and 12th dorsal, and the 5th lumbar. The—

Atlas (3)—is a bony ring supporting the head. A bony arch takes the

place of a body, and its spinous process is a mere tubercle. Its Lateral Masses (1) form its chief bulk, supporting large Articular Processes which look inward, the superior (2) articulating with the condyles of the occipital bone.

Axis (9)—is marked by its Odontoid Process (10) projecting upward from the body into the an-

terior part of the spinal foramen of the atlas, where it articulates with the anterior arch (3), and receives the occipito-axoid and the check ligaments. Its transverse processes (8) are very small and are not bifid. Its inferior articular surfaces (7) have the same direction as those of the other cervical vertebræ.

Vertebra Prominens—has a long and prominent spinous process which ends in a tubercle for the ligamentum nuchæ.

Dorsal Vertebræ. The 1st has one facet and a demifacet for the 1st and 2d ribs. The 9th has a demifacet only. The 1oth has but one facet on the body and one on the transverse process. The 11th and 12th have each but one facet on the body, and none on the transverse processes. The 12th resembles a lumbar vertebra in size and shape.

5th Lumbar Vertebra,—is much deeper in front than behind; its spinous process is small, but its transverse processes are large and thick, and point slightly upward.

#### Important Relations of Certain Vertebræ.

3d Cervical corresponds in situation to—the bifurcation of the common carotid artery, and the superior cervical ganglion.

5th Cervical, to—the junctions of the larynx with the trachea and the pharynx with the esophagus, and the middle cervical ganglion of the sympathetic.

2d Lumbar, to—the junction of the duodenum with the jejunum, the commencement of the thoracic duct and the portal vein, the origin of the superior mesenteric artery, the lower margin of the pancreas, the opening

of the ductus communis choledochus, the lower end of the spinal cord, and the crura of the diaphragm.

[The sacral and coccygeal vertebræ are described as bones of the pelvis.]

#### THE THORAX.

The Thorax is an osseo-cartilaginous cage formed by the bodies of the dorsal vertebræ posteriorly, the ribs and costal cartilages laterally, and the sternum in front. Its shape is conical, the axis inclined forward, the base below and closed by the diaphragm

Structures passing through its Apex, are—the trachea, œsophagus, large vessels of the neck, pneumogastric, phrenic and sympathetic nerves, thoracic duct, and in inspiration the apex of the lung.

Structures contained in its Cavity, are—the trachea, bronchi and lungs, the heart and great vessels, internal mammary arteries, azygos and bronchial

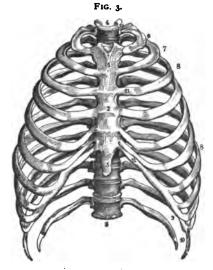

veins, pneumogastric, phrenic, and splanchnic nerves, œsophagus, thoracic duct. lymphatic vessels and glands.

The Sternum, or breast-bone, consists of 3 parts—the manubrium (1) or handle; the gladiolus (2), or sword; and the ensiform or xiphoid appendix (3). It presents the—

Interclavicular Notch,—on its superior border.

Manubrium (1),—articulates with the clavicle, 1st costal cartilage, and a part of the 2d.

Gladiolus (2), — articulates with the costal cartilages from the 3d to the 6th inclusive, and partly with the 2d and 7th.

Ensiform Appendix (3), the tip—articulates with the cartilage of the false ribs, and in part with the 7th costal cartilage. It is cartilaginous in youth.

Development and Muscles. The sternum is developed by 6 centres, reach for the manubrium and ensiform appendix and 4 for the gladiolus. The

muscles attached to it are 9 pairs and one single muscle,—the sterno-cleidomastoid, sterno-hyoid and sterno-thyroid, 3, to its upper part;—the rectus abdominis, external and internal oblique, transversalis and the diaphragm, 5, to its lower part;—the pectoralis major, 1, anteriorly;—and the triangularis sterni, 1, posteriorly.

The Ribs are 12 in number on each side, 7 of which are true ribs, being each connected to the sternum by a separate cartilage;—and 5 are jalse ribs. Three of the latter are connected by their cartilages to the cartilage of the 7th rib (11), while two are called floating ribs (10), having each one extremity free.

Characteristics Common to most of the Ribs. Each rib consists of a head, neck and shaft, and presents the following points, viz.—

- Head,—is divided by a ridge into 2 facets, which articulate with the facets on the bodies of the dorsal vertebræ; the ridge giving attachment to the interarticular ligament.
- Neck,—about an inch long, having attached to its upper border the anterior costo-transverse ligament, to its posterior surface the middle costo-transverse ligament; its anterior surface is smooth.
- Tuberosity,—at the junction of the neck with the shaft, has a facet for articulation with the transverse process of the next lower vertebra, and a rough surface for the posterior costo-transverse ligament.
- Shajt,—twisted on itself, is concave internally, convex externally, its upper border round and smooth, its lower border grooved for the intercostal vessels and nerves. At its external extremity is an oval depression for the insertion of the costal cartilage.
- Angle,—just in front of the tuberosity, is marked by a rough line, to which are attached the muscles of the deep layer of the back.

Development. Each rib has 3 centres, one each for the head, shaft, and tuberosity. The last 2 ribs, having no tuberosity, are developed each by 2 centres.

Peculiar Ribs, are the 1st, 2d, 10th, 11th, and 12th. They respectively present the following peculiarities—

- 1st Rib,—is broad, short, not twisted, has no angle, only one facet on the head; but on its upper surface are seen two grooves for the subclavian artery and vein, and between them a tubercle for the scalenus anticus muscle.
- 2d Rib,—is not twisted, its tuberosity and angle are very close together, and its upper surface presents rough surfaces for the serratus magnus and scalenus posticus muscles.
- 10th Rib,—has but one facet on its head.

11th Rib,—has no neck, no tuberosity, and but one facet on its head.
12th Rib,—has neither neck, angle, tuberosity nor groove, and but one facet.

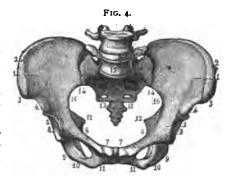

#### THE PELVIS.

The Pelvis is formed by the sacrum, coccyx, and two ossa innominata, and is divided into,—the *false pelvis*, comprising the upper and expanded portion,—and the *true pelvis*, below the ilio-pectineal line. The false pelvis corresponds to the iliac fossæ (1), and is marked by its walls being deficient anteriorly between the iliac borders, and posteriorly between the sacrum and the posterior iliac spines. The true pelvis has a—

Brim, or inlet,—bounded in front by the crest and spine of the pubes (7), behind by the promontory of the sacrum (15), laterally by the iliopectineal line. Its axis corresponds to a line from the umbilicus to the middle of the coccyx. Its average diameters in the female are,—4

inches antero-posteriorly, over 5 inches transversely, under 5 inches obliquely. In the male each of these measurements is about ½ an inch less.

Cavity,—is a short curved canal, connecting the brim with the outlet. In front its depth is about 1½ inches, posteriorly 4 to 4½ inches in the female, 4½ to 5½ inches in the male. Its

diameter is about 43 inches in the female, 42 inches in the male, all around.

Outlet,—is bounded by the pubic arch above (11), the tip of the coccyx behind, and the tuberosities of the ischia (9) laterally. Its axis, if prolonged, would touch the promontory of the sacrum. Its diameters in the female are each about 4½ inches, in the male about 3½ inches.

Chief Differences between the male and female pelves. The male pelvis is marked by strength of the bones, prominence of the muscular impressions, a deep and narrow cavity, and large obturator foramina. The female pelvis has lighter bones, broader iliac fossæ, the spines being further apart, greater diameters at every point, the sacrum less curved, and the pubic arch wider.

The Sacrum, or sacred bone, is triangular, curved, with its convexity backward, and is situated base upward between the ossa innominata, forming with the coccyx the posterior wall of the pelvis. The bone is formed by the coalescence of 5 vertebræ, and presents the following points, viz.—

Ridges (4),—four transversely across both surfaces, mark the union of its original segments.

Anterior Sacral Foramina,—eight for the anterior sacral nerves.

Grooves (5),—eight shallow and broad, for the aforesaid nerves.

Promontory,—at its junction with the last lumbar vertebræ.

Posterior Sacral Foramina,—eight for the posterior sacral nerves.

Tubercles,—representing the spinous processes of the segments.

Groove,—posteriorly, on each side of the spinous tubercles.

Cornua,—two at the posterior inferior portion of the bone.

Articular Surface (3),—on each side, articulates with the ilium.

Notch,—laterally and inferiorly, for the 5th sacral nerve.

Base (2),—has all the characteristics of the lumbar vertebræ, with the last of which it articulates.

Apex (16),—has an oval surface for articulation with the coccyx.

Sacral Canal,—the continuation of the spinal canal, is incomplete posteriorly at its lower end. It transmits the Cauda Equina; into it open the sacral foramina laterally.

The Coccyx consists of 4 (or 5) rudimentary vertebræ coalesced into a triangular bone, the base (1) of which articulates with the apex of the sacrum. Its posterior surface is rough for muscles and ligaments,

its anterior surface is smooth and marked by ridges at the junction of its constituent vertebræ. It presents the following points:-

Fig. 6.

Cornua (2),—two superiorly, articulating with the sacral cornua to form foramina for the 5th sacral nerves.

A pex,—is sometimes bifid and turned to one side.

The Ossa Innominata, or unnamed bones, are placed one on each side of the osseous pelvis, and are each formed by the union, about puberty, of 3 bones,—the ilium, ischium, and pubes. The innominate bone as a whole presents the following points, viz,-

Acetabulum, or cotyloid cavity,—receives the head of the femur. It is situated at the junction of the 3 bones externally, the ilium and ischium each forming about two-fifths, and the pubic bone one-fifth of it. A depression in its centre lodges a mass of fat containing vessels for the nourishment of the synovial membrane. The Cotyloid Notch is a deficiency in its lower anterior margin, transmitting nutrient vessels to the joint; to the edges of the notch is attached the ligamentum teres, and it is bridged over by the transverse ligament, a continuation of the cotyloid ligament which surmounts the brim of the acetabulum.

Obturator or Thyroid Foramen (8),—on the anterior surface between the pubes and ischium, large and oval in the male, small and triangular in the female; is closed by the obturator membrane, except above where the obturator nerves and vessels pass through it.

The Ilium is the superior part of the innominate bone, and presents the following points, viz.—

Crest (1),—along its upper border, having an outer and inner lip for muscular attachment, and ending in the superior spines.

Anterior Superior Spine (2),—to which are attached the sartorius and tensor vaginæ femoris muscles and Poupart's ligament.

Anterior Inferior Spine (4),—for the straight tendon of the rectus femoris.

Notch, between the above-named spines, transmitting the external cutaneous nerve, and lodging some fibres of the sartorius.

Posterior Superior Spine (19),—for the attachment of the erector spinæ muscle, and the oblique part of the sacro-sciatic ligament.

Posterior Inferior Spine (17),—for the great sacro-sciatic ligament.

Great Sacro-sciatic Notch (16),—below the

last-named spine, transmits the great sciatic, superior gluteal, and pudic nerves, the pyriformis muscle, and the sciatic, pudic, and gluteal vessels, also a nerve supplying the obturator externus muscle.

Curved Lines (21),—superior middle and inferior, on the outer surface of the bone, from the spaces between which arise the glutei muscles.

Groove,—above the acetabulum, for the reflected tendon of the rectus femoris muscle.

Linea Ilio-pectinea, in part,—on the inner surface, above which is a smooth surface, the Venter of the Ilium.

Articular Surjace (18),—rough, articulates with the sacrum.

The Ischium is the lowermost portion of the innominate bone, and presents the following points, viz.—

Body,—forms two-fifths of the acetabulum, and the external margin of the obturator foramen; on it is a broad groove for the tendon of the obturator externus muscle. Its posterior margin assists in forming the great sacro-sciatic notch.

Spine (14),—for the gemellus superior, coccygeus, and levator ani muscles, and the lesser sacro-sciatic ligament.

Lesser Sacro-sciatic Notch (13),—below the spine, transmits the obturator muscle, its nerve, and the pudic vessels and nerve as they re-enter the pelvis, having crossed the spine of the ischium. The sacro-sciatic notches are converted into foramina by the sacro-sciatic ligaments; the greater notch by the lesser ligament, the lesser notch by the greater ligament.

Tuberosity (12),—the lowest and most prominent part, gives attachment to the greater sacro-sciatic ligament, and to several muscles. On it one rests when sitting.

Ascending Ramus,—bounds the obturator foramen inferiorly, articulates with the descending ramus of the pubes, and gives attachment to the obturator membrane and several muscles.

The Pubes. The pubic or pectineal bone forms the anterior portion of the innominate. It presents the following points, viz.—

Body,—lies between the rami, and with its fellow forms the Symphysis, giving origin to several muscles and ligaments.

Crest (9),—is the upper part of the body, terminates externally in the Spine, and internally in the Angle.

Spine,—affords attachment to one end of Poupart's ligament.

Linea Ilio-pectinea, in part,—gives attachment to the conjoined tendon, Gimbernat's ligament, and the triangular ligament.

Horizontal Ramus,—forms part of the brim of the pelvis, of the margin of the obturator foramen, and of the acetabulum. On its under surface is a groove for the obturator vessels and nerve.

Pectineal Eminence (5),—gives attachment to the psoas parvus muscle.

Descending Ramus (11),—flat and thin, joins the ascending ramus of the ischium, and bounds the obturator foramen internally.

Muscles attached to the Os Innominatum number 36, comprising those of the abdomen, thigh, perineum, floor of the pelvis, and rotators of the hip-joint.

[By some anatomists the innominate bone is included among the bones of

the lower extremity, being considered analogous to the shoulder in the upper extremity.]

#### THE BONES OF THE HEAD.

#### THE FRONTAL BONE, (1, Fig. 8).

Points on its Vertical Portion, are as follows:-

Externally,—

Frontal Eminences,—one on each side of the median line.

Depression,—marking the site of the frontal suture before obliteration.

Superciliary Ridges,—behind which are the frontal sinuses.

Supraorbital Notches or Foramina,—in the supraorbital arches, at about their inner third, for the supraorbital vessels and nerves.

Nasal Eminence (24),—at lower end of the frontal depression.

External Angular Processes (13),—articulate with the malar bones and

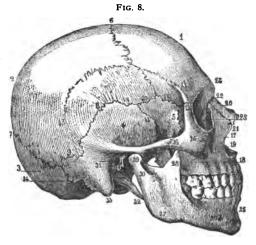

form the anterior part of the temporal ridges.

Internal Angular
Processes,—articulate with the
lachrymal bones.
Nasal Spine and
Notch,—between
the internal angular processes.

#### Internally,-

Groove,—for superior longitudinal sinus and the falk cerebri.

Frontal Crest,—for attachment of the falx cerebri.

Foramen Cæcum,—for a small vein to the longitudinal sinus.

Depressions and Elevations,—for convolutions of the brain.

Between the two tables of the vertical portion in the adult are the-

Frontal Sinuses,—two spaces at the anterior inferior part of the bone, which are lined with mucous membrane, and open into the middle meatus of the nose by means of an Infundibulum for each.

Describe its Horizontal Portion, or Orbital Plates. Each plate presents the following points,—

Fossa,—for the lachrymal gland, near the external angular process.

Depression,—at the nasal margin for the pulley of the superior oblique muscle.

Ethmoidal Notch,—having the following foramina on its margin.

Anterior Ethmoidal Foramen,—for the anterior ethmoidal vessels and the nasal branch of the ophthalmic nerve.

Posterior Ethmoidal Foramen, -- for posterior ethmoidal vessels.

Grooves,—on the cranial surface, for branches of the anterior and middle meningeal arteries.

Articulations, Development, and Muscles. The frontal bone articuates with 12 bones,—the sphenoid, ethmoid, 2 parietal, 2 nasal, 2 superior maxillary, 2 lachrymal, and 2 malar. It is developed by 2 centres in membrane, 1 for each lateral half. The muscles attached to it are 3 pairs,—the temporal, corrugator supercilii, and orbicularis palpebrarum.

#### THE PARIETAL BONES, (2, Fig. 8).

General Characteristics. They are 2 quadrilaterally-shaped bones situated at the superior and lateral regions of the cranium. The superior border of each joins the other by the Sagittal Suture, the anterior border joins the frontal bone forming the Coronal Suture (6); the posterior border articulates with the occipital, forming the Lambdoid Suture (7); the inferior border with the sphenoid (5) and temporal (4) bones. Forming the lateral walls of the skull they are named parietal, from paries, a wall.

Points on each Parietal Bone. Externally the bone is convex and presents for examination,—

Temporal Ridge (13),—continuous with the same on the frontal bone.

Parietal Eminence,—the point where ossification commenced.

Parietal Foramen,—close to the upper border, transmits a vein to the superior longitudinal sinus. Is not constant.

Internally, the bone is concave, and marked by-

Depressions,—for the Pacchionian bodies, and for the cerebral convolutions.

Furrows,—for branches of the middle meningeal artery.

Groove,—for the lateral sinus, at the posterior inferior angle.

Half-groove,—along the upper border, for the superior longitudinal sinus of the dura mater.

Articulations, Development, and Muscles. Each parietal bone articulates with 5 bones,—the frontal, occipital, sphenoid, temporal, and opposite parietal. It is developed from 1 centre in membrane. The only muscle attached to it is the temporal.

#### THE OCCIPITAL BONE, (3, Fig. 8).

General Features and Surfaces. It is trapezoidal in form, curved upon itself, and placed at the posterior and inferior region of the cranium. Externally its surface is convex and presents for examination the following, viz.—

External Occipital Protuberance (5), and Crest (4), for the attachment of the ligamentum nuchæ.

Superior and Injerior Curved Lines,—extending outward on each side of the external occipital crest.

Foramen Magnum (2),—transmitting the medulla oblongata and its mem-

branes, the vertebral arteries, and the spinal accessory nerves.

Condyles (6),—two in number, for articulation with the atlas vertebra.

Tubercles,—I on each condyle, for the check ligaments.

Anterior Condyloid Foramina, two for the hypoglossal nerves.

Posterior Condyloid Foramina (3),—two (often absent) for veins.

Jugular Processes (7),—two, each partly bounding the foramen lacerum posterius basis cranii.

Jugular Fossæ (8),—each form-

ing part of the foramen lacerum posterius basis cranii.

Internally, the surface is concave, showing—

Fossæ,—four for the cerebellar and posterior cerebral lobes.

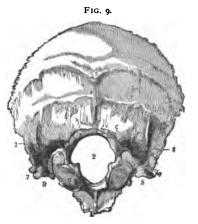

Internal Occipital Protuberance,—where 6 cranial sinuses meet to form the torcular (wine-press) Herophili.

Crucial Ridge,—the vertical portion for the falx cerebri and falx cerebelli; the transverse portion for the tentorium cerebelli, having also a groove for the lateral sinus.

Groove,—for the lateral sinus, and the inferior petrosal sinus, along the postero-lateral border.

Internal Openings—of the foramina described above.

Basilar Process (1) of the Occipital lies in front of the foramen mag-

num (2), articulates with the body of the sphenoid bone, smooth and grooved internally for the medulla oblongata and pons varolii, which lie upon it; rough inferiorly for the attachment of muscles, and presenting the—

Pharyngeal Spine,—for the attachment of the superior constrictor muscle of the pharynx and its tendinous raphé.

Articulations and Development. The occipital articulates with 6 bones,—the 2 parietal, 2 temporal, sphenoid, and atlas. It is developed by 4 centres, 1 each for the posterior part, the basilar process, and the 2 condyles; its ossification being completed about the 6th year of age.

Muscles attached to the Occipital Bone. There are 12 muscles attached on each side to the following portions, viz.—

Superior Curved Line 3,—the occipito-frontalis, trapezius, and sternocleido-mastoid muscles.

Space between the curved lines 2,—the complexus and splenius.

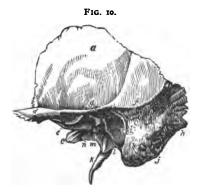

Space below the inferior curved line 3,—the obliquus capitis superior, rectus capitis posticus major and rectus capitis posticus minor.

Basilar Process 3,—the superior constrictor of the pharynx, rectus capitis anticus major and rectus capitis anticus minor.

Jugular Process 1,—the rectus capitis lateralis.

#### THE TEMPORAL BONES, (4 Fig. 8).

Situation and Divisions. They are situated at the inferior lateral portions of the skull, and contain the organs of hearing. Each bone is

divided into 3 parts, the Squamous (a) (scale-like), Mastoid (b) (nipple-like), and Petrous (c) (hard); and it is named from being the site of the first gray hairs (tempus, time).

The Squamous Portion is a semicircular plate, smooth externally, and grooved internally for the middle meningeal artery, with depressions for the cerebral convolutions. Externally are seen the—

Zygomatic Process (d), or Zygoma,—arising by 3 roots, and

extending forward to articulate with the malar bone.

Zygomatic Tubercle (e). at the base of the process, for the external lateral ligament of the lower jaw.

Eminentia Articularis,—formed by the anterior root of the zygoma.

Glenoid Fossa (g),—between the anterior and middle roots of the zygoma; its anterior part receives the condyle of the lower jaw, and is covered with cartilage; its posterior part lodges the parotid gland.

Glaserian Fissure,—divides the glenoid fossa; it transmits the laxator tympani muscle, the tympanic artery, and lodges the processus gracilis of the malleus.

Opening of the Canal of Hugier,—lies in the angle between the squamous and petrous portions of the bone; and transmits the chorda tympani nerve.

Temporal Ridge (f),-in part.

The Mastoid Portion projects like a nipple from the inferior portion of the bone posteriorly. Internally it is grooved for the lateral sinus (9); externally are seen the—

Mastoid Foramen (h),—the largest of several foramina, for a vein.

Mastoid Process,—at the tip, for the sterno-cleido-mastoid, splenius, and trachelo-mastoid muscles.

Digastric Fossa (j),—for the posterior belly of the digastric muscle.

Occipital Groove (8),—for the occipital artery.

Mastoid Cells,—in the interior of the mastoid process, open on the posterior wall of the middle ear, and are lined with mucous membrane.

The Petrous Portion is very hard, pyramidal in form, contains the internal and middle ear, projects inward and forward, and presents a base, an apex, three surfaces, and three borders.

On the Base are seen, the-

Meatus Auditorius Externus (i),
—the external opening of the
ear.

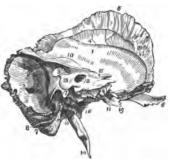

Auditory Process,—a bony ring for the external cartilage of the ear.

Apex lies internally, at the base of the skull, forming the outer boundary of the foramen lacerum medium, and contains the internal carotid canal.

Anterior Surface, presents from within outward—

Opening of the Carotid Canal (11),—for the internal carotid artery and plexus.

Depression,—for the Gasserian ganglion of the 5th pair of cranial nerves. Hiatus Fallopii,—for the great petrosal nerve, branch of the middle meningeal artery.

Foramen,-for the small petrosal nerve.

Eminence,—over the superior semicircular canal of the ear.

Depression,—over the tympanum.

Posterior Surface presents,-

Meatus Auditorius Internus (12),—transmits the 7th and 8th pairs of cranial nerves and the auditory artery, and lodges a process of dura mater.

Opening of the Aqueductus Vestibuli (13),—transmits to the vestibule a small artery and vein, and lodges a process of dura mater.

Inferior surface, presents from within outward-

Rough Quadrilateral Surjace (19),—for the origin of the tensor tympani and levator palati muscles.

Opening of the Carotid Canal,—transmitting the internal carotid artery, and the carotid plexus of the sympathetic nerve.

Aqueductus Cochlea,—transmitting an artery and vein to the cochlea.

Jugular Fossa,—a depression for the sinus of the internal jugular vein, forming with the occipital bone the foramen lacerum posterius, which transmits that vein and the 8th pair of cranial nerves, etc.

Foramen jor Jacobson's Nerve (tympanic branch of the glossopharyngeal),
—in the ridge between the jugular fossa and the carotid canal.

Foramen for Arnold's Nerve (auricular branch of the pneumogastric),—in the outer wall of the jugular fossa.

Jugular Surface,—for articulation with the jugular process of the occipital bone.

Vaginal Process (1),—ensheathing the root of the styloid process.

Styloid Process (14),—a long projection for the stylo-pharyngeus, stylo-hyoid, and stylo-glossus muscles; and the stylo-hyoid and stylo-maxillary ligaments, which are attached thereto.

Stylo-mastoid Foramen (15),—between the styloid and mastoid processes, for the exit of the facial nerve, and the entrance of the stylo-mastoid artery.

Auricular Fissure,—for the exit of Arnold's nerve.

In the angle between the petrous and squamous portions, are seen the-

Septum Tubæ,—a lamina separating the following canals. Its inner end projects into the tympanum, and is called the Processus cochlearijormis.

Opening—of the canal for the tensor tympani muscle.

Osseous Opening—of the Eustachian tube (n) inferiorly.

The Anterior Border articulates partly with the spinous process of the sphenoid bone.

 $\mathsf{Digitized}\,\mathsf{by}\,Google$ 

The Posterior Border assists in forming the jugular foramen, and is grooved for the inferior petrosal sinus.

The Superior Border separates the anterior fossa of the skull from the middle fossa; to it is attached the tentorium cerebelli, and it is grooved for the superior petrosal sinus (10).

Articulations and Development. The temporal articulates with 5 bones,—the occipital, parietal, sphenoid, malar, and inferior maxillary. It is developed by 4 centres, one each for the squamous portion, styloid process, and auditory process, and one for the petrous and mastoid portions. Its ossification is completed about the 2d or 3d year.

Muscles attached to it. There are 14 muscles attached to the following-named portions. To the—

Squamous Portion 2,—the temporal and masseter.

Mastoid Portion 6,—the occipito-frontalis, sterno-cleido-mastoid, splenius capitis, trachelo-mastoid, digastric, and retrahens aurem.

Petrous Portion 3,—the tensor tympani, levator palati, and stapedius.

Styloid Process 3,—the stylo-glossus, stylo-hyoid, and stylo-pharyngeus.

#### THE SPHENOID BONE, (5 Fig. 8).

**Position and Form.** Wedged in between the bones of the skull anteriorly, it resembles a bat with out-stretched wings. It is named from the Greek word  $\sigma\phi\eta\nu$ , a wedge, enters into the formation of 5 cavities, 4 fossæ, 3 fissures, and presents for description—

A Body. 2 Pterygoid Processes. 12 Foramina.
2 Greater Wings (2). 2 Styloid Processes. 12 pairs of Muscles.
2 Lesser Wings (1). 6 Clinoid Processes. 12 Articulations.
10 Points of Ossification. 3 Lesser Processes.

Body of the Sphenoid Bone. Placed in the median line, cuboid in shape, it presents on its UPPER SURFACE from before backward, the following points,—

Ethmoidal Spine (3),—articulating with the ethmoid bone.

Smooth Surjace,—grooved for the olfactory nerves.

 $\label{Optic Groove} Optic \ Groove, — supporting the commissure of the optic nerves.$ 

Olivary Process,—an olive-shaped eminence behind the optic groove.

Middle Clinoid Processes,—bounding the sella Turcica in front.

Sella Turcica (16) (Turkish saddle),—lodges the pituitary body and the circular sinus of the brain.

Dorsum Sellæ (back of the saddle),—grooved for the 6th nerves.

Posterior Clinoid Processes (6),—for attachment of the tentorium cerebelli. Grooves,—laterally, for the cavernous sinus and internal carotid artery.

POSTERIOR SURFACE is rough and quadrilateral (15): it articulates with the basilar process of the occipital bone, ossification being completed from the

Fig. 12.

18th to the 20th year of age.

Anterior Surface is nearly vertical, and presents the—
Lamella,—in the median line, articulating with the perpendicular plate of the ethmoid bone, and forming part of the nasal septum.

Openings of the Sphenoidal Sinuses (e),—cavities in the body of the bone which exist in adults, not in children.

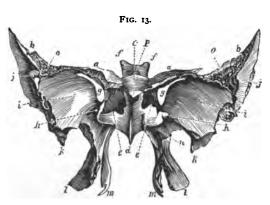

Sphenoidal Turbinated Bones (pyramids of Wistar),—which partially close the sinuses, and articulate with the ethmoid and palate bones.

INFERIOR SURFACE helps to form the nasal fossæ, and presents the-

Rostrum (d),—
which articulates with a
groove on the
vomer.

Vaginal Processes,—I on each side of the rostrum.

Pterygo-palatine
Grooves,—
which, with
the sphenoidal processes of the
palate bones,

form the pterygo-palatine canals, for the transmission of the pterygopalatine arteries and nerves.

Greater Wings of the Sphenoid. Each wing presents on its SUPERIOR SURFACE the following points,—

Foramen Rotundum (8),—for the superior maxillary division of the 5th nerve.

Foramen Ovale (9),—for the inferior maxillary-division of the 5th nerve, the small petrosal nerve, and the small meningeal artery.

Foramen Vesalii,—transmitting a small vein; often absent.

Foramen Spinosum (10),—transmitting the middle meningeal artery and veins, also sympathetic filaments from the cavernous plexus.

Anterior Surface assists in forming the external wall of the orbit, the spheno-maxillary and sphenoidal fissures. It articulates with the fronta and malar bones, and presents a—

Notch,-transmitting a branch of the ophthalmic artery.

Spine,—for part of the lower head of the external rectus muscle.

External Orbital Foramina,—transmitting arterial branches.

EXTERNAL SURFACE presents the following points,—

Pterygoid Ridge,—dividing the temporal fossa from the zygomatic.

Spine of the Sphenoid (11),—to which are attached the internal lateral ligament of the lower jaw, and the laxator tympani muscle.

CIRCUMFERENCE is partly serrated for articulation with the temporal and frontal bones, and partly smooth for the anterior margin of the foramen lacerum medium and the inferior margin of the sphenoidal fissure, which margins it assists in forming.

Lesser Wings (1) of the Sphenoid, or the Processes of Ingrassias (a),—terminate internally in the Anterior Clinoid Processes (5); their anterior borders articulate with the orbital plate of the frontal bone, the posterior are free, dividing the anterior cerebral fossa from the middle ones. Connected intimately with each of these wings are the—

Optic Foramen (4),—formed by the separation of its roots, and transmitting the optic nerve and the ophthalmic artery.

Sphenoidal Fissure (7), or Foramen Lacerum Anterius (g),—is bounded above by the lesser wing, below by the greater wing, and transmits the 3d, 4th, ophthalmic division of the 5th, and the 6th nerves, the ophthalmic vein, branches of the lachrymal and middle meningeal arteries, some filaments of the sympathetic nerve, and a process of the dura mater.

Pterygoid Processes of the Sphenoid. These wing-like processes descend, 1 on each side of the body, and divide each into 2 thin, bony plates (1m), connected together anteriorly, and presenting the—

Pterygoid Fossa,—between the plates posteriorly, the origin of the external pterygoid muscle.

Scaphoid Fossa,—at the base of the internal plate, serves as the origin of the tensor palati muscle.

Hamular Process,—a hook-like projection at the apex of the internal plate, around which plays the tendon of the tensor palati muscle.

Vidian Canal (14),—at the root of the process, for the Vidian nerve and vessels.

Triangular Notch,—at the end of the process, articulates with the pterygoid process of the palate bone.

What Bones articulate with the Sphenoid?—12, the other 7 bones of the cranium and 5 of the face,—the vomer, 2 malar, and 2 palate.

Development of the Sphenoid. By 10 centres, as follows.—2 for the greater wings, 2 for the lesser wings and anterior part of the body, 2 for the posterior part of the body, 2 for the pterygoid processes, and 2 for the sphenoidal turbinated processes. Ossification begins in the 2d feetal month, and is completed about the 11th year, by the union of the turbinated processes with the body.

Muscles attached to the Sphenoid.—12 pairs of muscles are attached to the sphenoid bone, as follows:—

Orbital muscles, 6-all except the inferior oblique of the eye.

Muscles of Mastication, 3—the temporal, external and internal pterygoids. Also the superior constrictor, tensor palati, and laxator tympani, 3.

### THE ETHMOID BONE.

General Characteristics. It is a spongy, light bone, depending from the ethmoidal notch of the frontal, and from between its orbital plates. It

consists of a body and 2 lateral masses, and is named from the Greek word  $\partial \theta \mu \rho \rho_0$ , a sieve.

Fig. 14.

Points on its Body. The body (b) consists of a horizontal or cribriform plate, and a perpendicular plate, and presents the—

Crista Galli (c),—or cock's comb, projecting upward, for the attachment of the anterior end of the falx cerebri.

Cribriform Plate (d),—on each side of the crista galli. It is concave for the olfactory bulbs (i), and perforated for the transmission of the olfactory nerves, the nasal branch of the ophthalmic nerve, and numerous small vessels.

Perpendicular Plate (a),—assists to form the

nasal septum, is usually inclined to one side, grooved for filaments

of the olfactory nerves, and has attached to it the cartilage of the nose.

Lateral Masses. They consist of a number of cellular cavities, and each one presents the following points,—

Ethmoid Cells,—the anterior opening by the infundibulum into the middle meatus of the nose, the posterior into the superior meatus.

Os Planum (h), or orbital plate,—helps to form the inner wall of the orbit and is notched superiorly to form with the frontal bone the two ethmoidal foramina.

Unciform Process,—descends to articulate with the inferior turbinated, and forms part of the inner wall of the antrum.

Superior Turbinated Process (f),—curves downward and outward.

Middle Turbinated Process (g),—is larger and more curved than the superior. These processes bound the superior meatus of the nose, and are often called the superior and middle turbinated bones.

Articulations, Development, and Muscles. The ethmoid articulates with 15 bones, viz.—all those of the face except the malar, and the frontal and sphenoid of the cranium. It is developed by 3 centres, 1 for each lateral mass, and 1 for the body, ossification being completed about the 6th year. There are no muscles attached to it.

# THE NASAL BONES, (20 Fig. 8).

The Nasal are 2 small bones forming the bridge of the nose by articulation

with each other in the median line (4). From side to side they are convex externally and concave internally, where they are grooved longitudinally for the external branch of the nasal nerve and some small arteries. They are perforated about the centre by a foramen (1), for a small tributary to the facial vein. The superior border (2) articulates with the nasal notch of the frontal bone; the injerior border (3) serves for the attachment of the lateral cartilage of the nose. The external border (5) articulates with the nasal process of the superior maxillary; the internal border (4) with its fellow, with the nasal spine of the frontal above and with the ethmoid bone below.

They are each developed by one centre of ossification, and have no muscles attached to them except a few fibres of the occipito-frontalis.

### THE SUPERIOR MAXILLARY BONES, (18 Fig. 8).

The Superior Maxillary are 2 hollow bones, together forming the upper jaw. Each bone consists of 4 processes, and a body which possesses interiorly a large cavity, the antrum of Highmore.

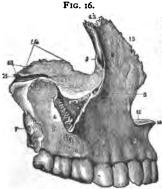

Antrum of Highmore is a pyramidal cavity in the body of the bone, which opens into the middle meatus of the nose by an aperture which is very small in the recent subject, admitting only a small probe. Its walls are very thin, and are covered internally by mucous membrane. It presents the—

A perture,—partly closed by the articulation of the unciform process of the ethmoid with the ethmoidal process of the inferior turbinated, and that of the maxillary process of the palate with a fissure in the superior maxillary; also by the maxillary process of the inferior turbinated which hooks over the lower edge of the orifice.

Posterior Dental Canals,—on the posterior wall of the cavity.

Processes—in its floor, formed by the alveoli of the 1st and 2d molar teeth, the roots of which occasionally perforate it.

Other Points presented by the body. The body has 4 surfaces, the

facial externally, the zygomatic posteriorly, the orbital superiorly, and an internal surface forming part of the outer wall of the nose and the cavity of the mouth. It presents the—

Incisive Fossa (2),—on the facial surface, above the incisor sockets, for the origin of the depressor alæ nasi muscle.

Canine Fossa (1),—more externally, for the levator anguli oris muscle.

Infraorbital Foramen (3),—above the canine fossa, transmitting the infraorbital vessels and nerve, from the infraorbital canal in the orbital surface of the bone.

Maxillary Tuberosity (7),—articulates with the tuberosity of the palate bone.

Turbinated Crests,—inferior and superior, on the inner surface, bounding horizontal grooves which correspond to the meati of the nose.

Vertical Grooves,—on the inner surface, one assisting to form the nasal duct, the other to form the posterior palatine canal.

Rough Surjace,—for articulation with the palate bone.

Orbital Surface,—articulating with the lachrymal, ethmoid, and palate bones interiorly, partly bounding the spheno-maxillary fissure exteriorly, and forming the lower margin of the orbit anteriorly.

Infraorbital Groove (11),—along the orbital surface, ending in the infraorbital canal and foramen. (See above.)

Depression,—for the origin of the inferior oblique muscle of the eye.

Processes of the Superior Maxillary are 4 in number, as follows.—

MALAR or PYRAMIDAL PROCESS (4, 5),—is triangular, looks outward from the body, and is rough for articulation with the malar bone.

NASAL PROCESS (8),—is thin anteriorly and serrated superiorly (12) for articulation with the nasal bone; posteriorly it is smooth and articulates with the lachrymal. It presents the—

Turbinated Crests,—superior and inferior, the former articulating with the middle turbinated process of the ethmoid bone.

Outer Surface,—gives origin to the orbicularis palpebrarum and levator labii superioris alæque nasi muscles, and the tendo oculi.

Groove—on the posterior border (9), helping to form the nasal duct.

ALVEOLAR PROCESS (6),—forms the curved line of the teeth, and presents— Alveoli,—or sockets, for 8 teeth in the adult, 5 in the child.

PALATE PROCESS,—forms part of the floor of the nasal cavity, and the roof of the mouth. It articulates with the vomer, the palate bone, and with its fellow process, and presents the—

Incisive Foramen, or Foramen of Stenson,—leading into the anterior palatine canal, for the terminal branches of the posterior palatine arteries.

Foramina of Scarpa, 2,—transmitting the naso-palatine nerves.

Groove,—on the under surface, for the protection of the vessels and nerves.

Orifice—of the posterior palatine canal, at the posterior end.

Nasal Crest,—at the articulation of the two processes with the vomer.

Anterior Nasal Spine (10),—the anterior extremity of the nasal crest.

Articulations and Development. The superior maxillary articulates with 9 bones,—the frontal (12), ethmoid (14), vomer (13), nasal (15), lachrymal, malar, palate, inferior turbinated, and opposite superior maxillary. It is developed probably by 4 centres,—I for the facial and nasal parts, another for the orbital and malar, a 3d for the incisive, and a 4th for the palate portion.

Muscles attached to it, are II, viz.—the orbicularis palpebrarum, and levator anguli oris alæque nasi, 2, to the nasal process;—the levator labii superioris, levator anguli oris, compressor naris, depressor alæ nasi, orbicu-

laris oris, and inferior oblique of the eye, 6, to the body;—the buccinator, 1, to the alveolar process;—the masseter, 1, to the malar process;—and the external pterygoid, 1, to the tuberosity.

### THE LACHRYMAL BONES.

The Lachrymal are 2 small quadrilateral-shaped bones, situated in the anterior part of the inner wall of the orbit. Each bone presents a—

Groove (3),—on the external surface, forming part of the nasal duct.

Ridge (1),—also externally, for attachment of the tensor tarsi muscle.

Furrow,—internally, corresponding to the ridge on the external surface.

6 6 2

FIG. 17.

Hamular Process (2),—projecting downward to articulate with the lachrymal process of the inferior turbinated bone.

Superior Border (8),—articulates with the internal angular process of the frontal bone.

Inferior Border (9),—articulates anteriorly with the lachrymal process of the inferior turbinated bone.

Anterior Border (6),—articulates with the nasal process of the superior maxillary bone.

Posterior Border (7),—articulates with the os planum of the ethmoid bone.

Internal Surface, -closes the anterior ethmoidal cells.

Articulations, Development, and Muscles. The lachrymal articulates with 4 bones,—the frontal, ethmoid, superior maxillary, and inferior turbinated. It is developed from 1 centre, and has but 1 muscle attached to it, the tensor tarsi or Horner's muscle.

# THE MALAR BONES, (14 Fig. 8).

The Malar or cheek bones are situated at the outer and upper part of the face, aiding to form the cavities of the orbits and the temporal and zygomatic fossæ. Each bone presents an—

External Surjace,—convex, for attachment of the zygomatic muscles.

Foramen,—externally, for the malar branch of the temporo-malar nerve.

Foramen (c),—internally, for the temporal branch of the same nerve.

Fron: al Process (a),—articulates with the external angular process of the frontal.

Orbital Process,—projecting backward, forming part of the floor and outer wall of the orbit, as well as part of the temporal fossa, and bounds the spheno-maxillary fissure anteriorly.

Zygomatic Process (f),—projecting backward to articulate with the zygomatic process of the temporal bone by a serrated edge.

Upper Border (b),—forms the outer and inferior margin of the orbit.

Fig. 18.

Anterior Border (d),—articulates with the superior maxillary bone.

Posterior Border (h),—terminates the temporal fossa below.

Articulations, Development, and Muscles. The malar articulates with 4 bones,—the frontal, sphenoid, temporal, and superior maxillary. It is developed by one centre of ossification, and has 4 muscles attached to it,—the levator labii superioris, zygomaticus major and minor, and the masseter.

#### THE PALATE BONES.

The Palate Bones are 2 irregularly-shaped bones, situated posteriorly in the nares. Each bone assists in forming the floor and outer wall of the nose, the roof of the mouth, the floor of the orbit, the inner wall of the antrum, the zygomatic, spheno-maxillary, and pterygoid fossæ, and presents the following points:—

HORIZONTAL PLATE (a), completes the nasal floor and hard palate; has a—
Ridge,—on the inferior surface, for the tensor palati aponeurosis.

Groove,—assisting to form the posterior palatine canal.

Foramina,—transmitting the anterior and posterior palatine nerves.

Anterior Border,—is serrated, and joins the superior maxillary bones.

Posterior Border,—is free and concave, for the attachment of the soft palate.

Inner Border (d),—is thick, and articulates with its fellow, forming a groove for the reception of the vomer. Its posterior extremity is the—Posterior Nasal Spine,—for the origin of the azygos uvulæ muscle.

VERTICAL PLATE (b), a broad and thick lamella, presents the following:—

Superior Turbinated Crest,—on the inner surface. Below it is the—

Inferior Turbinated Crest (g),—dividing the middle meatus of the nose from the inferior, and articulating with the inferior turbinated bone.

Posterior Border,—articulates with the pterygoid process of the sphenoid. Groove,—on the external surface, helping to form the posterior palatine canal.

Two Smooth Surfaces,—externally, one forming the inner wall of the zygomatic fossa; the other, part of the inner wall of the antrum.

Two Rough Surfaces,—also externally, one for articulation with the superior maxillary; the other with the pterygoid process of the sphenoid.

FIG. 19.

Deep Notch,—which by articulation with the sphenoid bone, forms the spheno-palatine joramen (h),—for the spheno-palatine vessels and the superior nasal and palatine nerves.

PTERYGOID PROCESS (c), is wedged into the notch between the plates of the pterygoid process of the sphenoid, with which it articulates laterally. In it are the—

Palatine Foramina,—for the anterior, middle and posterior palatine nerves.

Posterior Surface,—aids in forming the pterygoid fossa.

Orbital process (i),—triangular in shape, large and hollow. It has—

Three Articular Surfaces,—for the sup. maxillary, sphenoid, and ethmoid.

Two Free Surfaces,—the orbital forming part of the floor of the orbit, the external aiding to form the zygomatic fossa.

Rounded Border,—forms a part of the spheno-maxillary fissure.

SPHENOIDAL PROCESS (j), projects backward, articulates superiorly with the body of the sphenoid, and externally with the pterygoid process of the sphenoid. On its upper surface is a—

Groove,—which assists in forming the pterygo-palatine canal. Inner Surface,—forms part of the outer wall of the nasal fossa.

Articulations, Development, and Muscles. The palate articulates with 6 bones,—the sphenoid, ethmoid, vomer, superior maxillary, inferior turbinated, and its fellow palate bone. It is developed by one centre at the junction of the two plates. There are 4 muscles attached to it,—the azygos uvulæ, internal pterygoid, superior constrictor and tensor palati.

### THE INFERIOR TURBINATED BONES.

The Inferior Turbinated Bones are 2 thin, curved osseous plates situated in the nasal fossæ, their convex surfaces presenting inwardly. Each bone is attached above to the inferior turbinated crests of the superior maxillary and palate bones, and

presents the following, viz.—

Lachrymal Process (3),—aiding to form the nasal duct, by articulation with the lachrymal and superior maxillary bones.

Ethmoidal Process (1)—articulating with the unciform process of the ethmoid, thus helping to partially close the aperture of the antrum.

Maxillary Process (4),—also helps to partially close the aperture of the antrum, by hooking (7) over the lower edge of that orifice.

Free Border (5),—below, coming to about ½ inch above the floor of the nose.

Articulations, Development and Muscles. The inferior turbinated articulates with 4 bones, the ethmoid, lachrymal, palate, and superior maxillary. It is developed by one centre, and has no muscles attached to it.

#### THE VOMER.

The Vomer (plough-share) forms the postero-inferior part of the nasal septum, but is usually bent to one side. Its—

Superior Border (1, 2),—has a groove and two alæ or wings, for articulation with the rostrum and vaginal processes of the sphenoid bone.

Anterior Border (3),—is grooved for the ethmoidal plate and the nasal cartilage.

Inferior Border (4),—the longest, articulates with the nasal crest of the superior maxillary and palate bones.

Posterior Border,—is free and presents toward the pharynx.

Naso-palatine Grooves,—laterally, for the naso-palatine nerves.

Furrows,—on the lateral surfaces (6), for vessels and nerve-filaments.

FIG. 21.

Articulations, Development and Muscles. The vomer articulates with 6 bones,—the sphenoid, ethmoid, 2 superior maxillary, and 2 palate bones. It is developed by one centre, which appears about the 6th feetal week in cartilage between two laminæ which coalesce after puberty. It has no muscles attached to it.

# THE INFERIOR MAXILLARY BONE, (25 Fig. 8).

General Characteristics. The Inferior Maxillary Bone (the Mandible) forms the lower jaw, receives the inferior teeth, and is the second bone of the body in which ossification appears, the clavicle being the first. It consists of a body and two rami.

The Body (1) is shaped somewhat like a horseshoe, and presents for examination the following:—

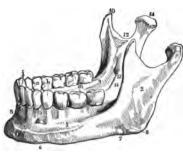

Alveolar Portion (15),—above the oblique line, containing on its upper border alveoli for 16 teeth in the adult, for 10 in the child (i, b, c, m).

Symphysis (3),—a vertical ridge on the median line, marking the junction of the two symmetrical portions of which the bone originally consisted.

Mental Process,—a prominent triangular eminence, forming the chin.

Externally on each side from the symphysis backward, are the—
Incisive Fossa (4),—above the chin, for the origin of the levator menti.

FIG. 22.

Mental Foramen (5),—below the 2d bicuspid alveolus, transmitting the mental artery and nerve.

External Oblique Line (1),—for the origins of the depressor labii inferioris and depressor anguli oris muscles from its anterior half.

Groove (7),—near the angle, for the facial artery.

Internally, on each side from the median depression backward, are the—

Genial Tubercles,—the superior for the genio-hyo-glossus muscle; the inferior for the genio-hyoid.

Mylo-hyoid Ridge,—obliquely backward, for the mylo-hyoid muscle. Sublingual Fossa,—near the genial tubercles, for the sublingual gland. Fossa,—below the sublingual, for the anterior belly of the digastric muscle. Submaxillary Fossa,—below the ridge, for the submaxillary gland.

The Rami of the Inferior Maxillary, the ascending portions of the bone, are 2 in number, and each presents the—

Coronoid Process (10),—anteriorly, for the insertion of the temporal muscle.

Condyloid Process (11),—posteriorly. Its condyle articulates with the glenoid fossa of the temporal bone, its neck receives the insertion of the external pterygoid muscle, its tubercle has attached to it the external lateral ligament of the lower jaw.

Sigmoid Notch (12),—a deep depression separating the above-named processes from each other, and crossed by the masseteric vessels and nerve.

Groove,—on the coronoid process internally, and prolonged downward upon the body, for the attachment of the buccinator muscle.

Ridges,—on the external surface, for the insertion of the masseter.

Spine,—a projection on the internal surface, for the attachment of the internal lateral ligament of the jaw.

Inferior Dental Canal (13),—opening behind the spine, lies within the ramus and body of the bone for the inferior dental vessels and nerve. It communicates with each alveolus and with the mental foramen.

Mylo-hyoid Groove (14),—below the spine, for the mylo-hyoid vessels and nerve.

Rough Surface,—behind the groove, for the internal pterygoid muscle.

Angle of the Jaw (8),—at the junction of the posterior border of the ramus with the inferior border of the body, for the insertion of the masseter and internal pterygoid muscles, and the stylo-maxillary ligament.

Articulations and Development. It articulates with one pair of bones—the temporal. It is the earliest formed bone in the body except the clavicle, and is probably developed by 2 centres, one for each lateral half, the two halves coalescing at the symphysis about the 1st year of age. In adult life the ramus arises almost vertically from the body, and the dental canal lies about the middle of the body. In old age the ramus extends obliquely backward, the angle becoming very obtuse; and the alveolar portion being absorbed, the dental canal is near the superior border.

Muscles attached to the Inferior Maxillary,—number 15 pairs,—the masseter, internal and external pterygoids and temporal, 4, to the ramus;—the genio-hyo-glossus, genio-hyoid, mylo-hyoid, digastric, and superior constrictor, 5, to the internal surface of the body;—the depressor labii inferioris, depressor anguli oris, levator menti, orbicularis oris, platysma myoides, and buccinator, 6, to the external surface of the body.

#### THE ORBITS.

The Orbits are 2 conoidal cavities, situated between the forehead and the face, their bases outward, their apices pointing backward, the lines of axial prolongation meeting at the sella turcica of the sphenoid bone. They contain the organs of vision with their appendages, and are each formed by 7 bones,—the frontal (1), ethmoid (2), sphenoid (3, 4, 5), lachrymal (6), superior maxillary (7), palate (8), and malar (9), of which the first three are common to both orbits. Each orbit communicates with 1 cavity and 4 fossæ, as follows, viz.—

Cavity of the cranium,—by the optic foramen (11) and sphenoidal fissure (10).

Fossæ (4)—the nasal, temporal, zygomatic, and spheno-maxillary,—by the nasal duct (12) and the spheno-maxillary fissure (13).

Foramina communicating with each orbit are 9 in number,—the optic foramen (11), sphenoidal fissure (10), anterior (21) and posterior (22) ethmoidal foramina, supraorbital (14), infraorbital (15), and malar foramina (16), the nasal duct (12), and the spheno-maxillary fissure (13).

Roof of the Orbit is formed by the orbital plate of the frontal bone ante-

riorly (1), and the lesser wing of the sphenoid (4) posteriorly. It is concave, and presents the—

Lachrymal Fossa (17),—at its outer angle, for the lachrymal gland.

Depression (18),—at the inner angle, for the pulley of the superior oblique.

Floor of the Orbit is formed by the orbital surface of the superior maxillary bone (7), and the orbital process of the malar(9) and palate bones (8).

It is nearly flat and presents the— Palato-maxillary Suture—posteriorly.

Infraorbital Canal,—and a Depression for the superior oblique muscle of the eye, anteriorly.

Infraorbital Groove (19),—posteriorly.

Inner Wall of the Orbit is

formed by the nasal process of the superior maxillary bone (20), the lachrymal (6), the os planum of the ethmoid (2), and the body of the sphenoid (3). It presents—

A Groove,—for the lachrymal sac, and the Lachrymal Crest, anteriorly.

2 Sutures,—the ethmo-lachrymal, and the ethmo-sphenoidal.

Outer Wall of the Orbit is formed by the orbital process of the malar bone (9), and the greater wing of the sphenoid (5). It presents the Orifices (16) of the malar canals, and the Spheno-malar Suture.

Angles of the Orbit present the following points:-

IN THE SUPERIOR EXTERNAL ANGLE:-

Sphenoidal Fissure (10), or Foramen Lacerum Anterius,—transmits the 3d, 4th, ophthalmic division of the 5th, and the 6th nerves, the ophthalmic vein, branches of the lachrymal and middle meningeal arteries, filaments of the sympathetic nerve, and a process of the dura mater.

Articulations,—the fronto-malar, and fronto-sphenoidal.

In the superior internal angle:-

Suture,—the lachrymo-ethmo-frontal, in which are the following foramina: Anterior Ethmoidal Foramen (21),—transmitting the anterior ethmoidal artery and the nasal nerve.

Posterior Ethmoidal Foramen (22),—transmitting the posterior ethmoidal artery and vein.

IN THE INFERIOR EXTERNAL ANGLE:-

Spheno-maxillary Fissure (13)—(described under the Zygomatic Fossa).

IT THE INFERIOR INTERNAL ANGLE:-

A Suture,—the ethmo-maxillo-palato-lachrymal.

Other Points connected with the Orbit are two, the supraorbital notch and the optic foramen, as follows,—

Supraorbital Notch or Foramen (14),—at the junction of the inner and middle thirds of the upper circumference, transmitting the supraorbital artery, veins, and nerve. A line prolonged from this notch through the interval between the bicuspid teeth of either jaw, will cross both the infraorbital and mental foramina, and the canine fossa of the superior maxillary bone.

Optic Foramen (11),—at the apex, is formed by the 2 roots of the lesser wing of the sphenoid, and transmits the optic nerve and the ophthalmic artery. From around its margin arises a tendinous ring, the common origin of the 4 recti muscles of the eye.

Muscles arising within the Orbit are the 4 recti and 2 oblique of the eye, the levator palpebræ, and the tensor tarsi (8 in all).

### THE FOSSÆ.

The Nasal Fossæ together form the cavity of the nose, being separated from each other by the Septum Nasi (11). They open in front by the anterior nares, behind by the posterior nares; and extend from the palate processes of the superior maxillary and palate bones (17), upward to the base of the cranium. They are formed by 14 bones,—the ethmoid, sphenoid, frontal, vomer, 2 nasal, 2 superior maxillary, 2 lachrymal, 2 palate, and 2 inferior turbinated.

The Septum Nasi (11) forms the inner wall of each nasal fossa, and is formed chiefly by the perpendicular plate of the ethmoid bone, the vomer, and the triangular cartilage of the septum; to a less extent by 5 other bones,—the rostrum of the sphenoid, the nasal spine of the frontal, and the crests of the nasal, palate, and superior maxillary bones.

Points presented by each Nasal Fossa are as follows:—

On the roof:-

Openings,-posteriorly, into the sphenoidal sinuses.

Olfactory Foramina,—and the Nasal Slit, in the cribriform plate of the ethmoid bone.

ON THE FLOOR:-

Orifice,—of the anterior palatine canal.

Suture,—between the bones forming the hard palate.

Nasal Spine,—anterior and posterior, and the Ridge connecting them.

On the outer wall, from above downward:-

Superior Turbinated Process,—of the ethmoid.

Superior Meatus of the nose—into which open 3 orifices,—those of the pos-

FIG. 24.

terior ethmoidal and the sphenoidal sinuses, and the sphenopalatine foramen.

Middle Turbinated Process (7),—of the ethmoid.

Middle Meatus of the nose,—into which open 2 orifices, those of the antrum (14) and infundibulum, the latter draining the anterior ethmoidal cells (8), and the frontal sinus.

Inferior Turbinated Bone (10), below which is the—

Inferior Meatus—of the nose, the largest; into it open 2 orifices

those of the lachrymal, and anterior palatine canals. To these may be added the anterior and posterior nares.

The Temporal Fossa. Situated on each side of the cranium, it is shallow above and behind, but deep in front and below, and is formed by parts of 5 bones,—the frontal, sphenoid, temporal, parietal, and malar. It is bounded above and behind by the temporal ridge, in front by the malar, frontal, and sphenoid bones, and below by the zygoma and the pterygoid ridge on the greater wing of the sphenoid. It is traversed by 6 sutures,—the sphenomalar, spheno-frontal, spheno-parietal, spheno-temporal, fronto-parietal, and temporo-parietal. It opens below into the zygomatic fossa; and lodges the temporal muscle, and the deep temporal vessels.

The Zygomatic Fossa extends downward from the temporal fossa, and is bounded —

In front,—by the tuberosity of the superior maxillary bone.

Externally,—by the zygoma, and the ramus of the inf. maxillary.

Internally,—by the external plate of the pterygoid process.

Avove,—by the temporal fossa, the squamous portion of the temporal bone and the greater wing of the sphenoid.

Below,—by the alveolar border of the inferior maxillary bone.

### Fissures opening into the Zygomatic Fossa are two, the-

Spheno-maxillary Fissure,—between the greater wing of the sphenoid externally, and the superior maxillary and palate bones internally. It connects the orbit with the zygomatic, temporal, and spheno-maxillary fossæ; and transmits the infraorbital artery, the superior maxillary nerve and its orbital branches, and the ascending branches of Meckel's ganglion.

Pterygo-maxillary Fissure,—between the tuberosity of the superior maxillary bone and the pterygoid process of the sphenoid. It transmits branches of the internal maxillary artery, and connects the zygomatic fossa with the spheno-maxillary.

The Spheno-Maxillary Fossa is a triangular cavity between the pterygoid process of the sphenoid bone and the tuberosity of the superior maxillary, and is situated at the junction of the spheno-maxillary, pterygo-maxillary, and sphenoidal fissures. Into it open—

- 3 Fossæ,—the orbital, zygomatic, and nasal.
- 2 Cavities,—the cranial, and buccal.
- 5 Foramina,—the Vidian and pterygo-palatine canals and the foramen rotundum, posteriorly; the spheno-palatine foramen on the inner wall; and the posterior palatine canal inferiorly, occasionally also the accessory palatine canals.

### THE SUTURES AND FONTANELLES.

The Sutures of the Skull are 13 in number, as follows:-

At the vertex of the skull are 3, the-

Sagittal or Interparietal,—formed by the junction of the two parietal bones. Coronal or Fronto-parietal,—extends transversely across the vertex of the skull anteriorly.

Lambdoid or Occipito-parietal,—extends transversely across the vertex of the skull posteriorly.

At the sides of the skull are 5, the-

Fronto-malar and Fronto-sphenoidal,—anteriorly.

Spheno-parietal, Squamo-parietal and Masto-parietal, -posteriorly.

At the base of the skull are 5, the-

Basilar,—in the central line of the base.

Petro-occipital, Masto-occipital, Petro-sphenoidal and Squamo-sphenoidal,
—on each side.

The Facial Sutures are very numerous, the most important being the following:—

Zygomatic Suture,—at the temporo-malar articulation.

Transverse Suture,—extending from one external angular process of the frontal bone across to the other, and connecting that bone with the malar, sphenoid, ethmoid, lachrymal, superior maxillary, and nasal bones.

Symphysis of the Chin,—the site of a feetal suture.

The Sutures are formed by dentations of the external tables interdigitating with each other, the adjacent edges of the internal tables lying in unjoined proximity. The sutures are not formed until a long time after the formation of the skull, probably to permit of the marginal growth of the bones.

The Fontanelles are 6 membranous intervals in the infant's skull, corresponding in situation with the angles of the two parietal bones. They are as follows:—

Anterior,—at the junction of the sagittal and coronal intervals.

Posterior,—at the junction of the sagittal and lambdoid intervals.

Lateral Fontanelles, 4,—two at the anterior inferior angles, and two at the posterior inferior angles of the parietal bones.

The Wormian Bones are supernumerary small pieces of bone, irregularly shaped, and developed by special centres in unclosed portions of the cranial sutures and fontanelles, being most frequent in the lambdoid suture. They are also called "ossa triqueta" from their triangular form.

The Hyoid Bone is shaped like a horse-shoe and has no articulation with the skeleton, but supports the tongue. It consists of a Body, two greater, and two lesser Cornua or horns. On the body is a Crucial Ridge, with a Tubercle at the centre. It is developed by 5 centres,—one for the body and one for each horn. Attached to it are 10 muscles, 3 ligaments and 1 membrane, as follows:—

To the Body,—the genio-, mylo-, stylo-, sterno-, thyro-, omo-hyoid, the genio-hyo-glossus, and the hyo-glossus muscles; also the pulley of the digastric, the hyo-epiglottic ligament, and the thyro-hyoid membrane.

To the Greater Cornu,—the hyo-glossus, middle constrictor muscles, and part of the thyro-hyoid; also the thyro-hyoid ligament.

To the Lesser Cornu,—the stylo-hyoid ligament.

### FORAMINA AT THE BASE OF THE SKULL.

with the various structures transmitted by each foramen.

Internally, the Anterior Fossa has r single and 4 pairs, viz.—

Foramen Cacum,—lodges a fold of dura mater, and transmits a vein to the

longitudinal sinus from the nose, sometimes one from the frontal sinus.

Ethmoidal Fissure,—the nasal branch of the 5th nerve.

Olfactory,—olfactory nerves, and nasal branches of the ethmoidal arteries.

Anterior Ethmoidal,—ant. ethmoidal artery and the nasal br. of the 5th nerve.

Posterior Ethmoidal, -posterior ethmoidal artery and vein.

Middle Fossæ contain 10 foramina in each fossa, viz.-

Optic Foramen,—optic nerve and ophthalmic artery.

Foramen Lacerum Anterius, or Sphenoidal Fissure,—the 3d, 4th, ophthalmic division of the 5th, and the 6th cranial nerves and filaments of the sympathetic; ophthalmic vein, a branch of the lachrymal artery, orbital branches of the middle meningeal artery, and a process of dura mater.

Foramen Rotundum,—superior maxillary division of the 5th nerve.

Foramen Vesalii,—a small vein. This foramen is often absent.

Foramen Ovale,—inferior maxillary division of the 5th nerve, lesser petrosal nerve, and the small meningeal branch of the internal maxillary artery.

Foramen Spinosum,—middle meningeal artery, meningeal veins, and sympathetic filaments from the cavernous plexus.

Foramen Lacerum Medium,—internal carotid artery, carotid plexus, Vidian nerve, and a branch from the ascending pharyngeal artery.

Small Foramina,—for the small and external superf. petrosal nerves.

Hiatus Fallopii,—large petrosal nerve, branch of middle meningeal artery.

Posterior Fossa contains 6 pairs and 1 single foramen, viz.-

Meatus Auditorius Internus,—facial and auditory nerves, auditory artery. Aquæductus Vestibuli,—small artery and vein, process of dura mater.

Foramen Lacerum Posterius, (Jugular Foramen),—the glosso-pharyngeal, pneumo-gastric, and spinal accessory nerves, internal jugular vein, meningeal branches of the ascending pharyngeal and occipital arteries.

Mastoid Foramen (often absent),—a small vein, also occasionally the mastoid artery.

Anterior Condyloid Foramen,—hypoglossal nerve, meningeal branch from the ascending pharyngeal artery.

Posterior Condyloid Foramen (often absent),—posterior condyloid vein.

Foramen Magnum,—medulla oblongata and its membranes, the vertebral arteries, and the spinal accessory nerves.

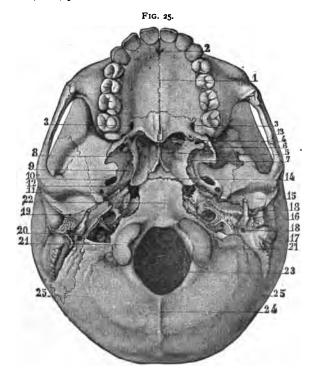

Externally, at the base of the skull, from the front backward, are 22 foramina on each side, and I single, the foramen magnum, as follows:—

Foramina of Scarpa (2) (Anterior Palatine), 2 in the median line,—for the naso-palatine nerves.

Foramina of Stenson (2) (Incisive), laterally,—terminal branches of the posterior palatine arteries.

Posterior Palatine (3),—posterior palatine vessels, anterior palatine nerve.

Accessory Palatine Foramina (1 or 2 on each side),—the middle and posterior (small) palatine nerves.

Orifice of the Posterior Naris,—air to the lungs.

Pterygo-palatine Foramen,—pterygo-palatine vessels.

Foramen Ovale (10),—see above, under Middle Fossæ.

Orifice of the Vidian Canal,—the Vidian nerve and vessels.

Foramen Spinosum (11),—see above, under Middle Fossæ.

Foramen Lacerum Medium (12),—see above, under Middle Fossæ.

Opening for the Eustachian Tube,—air to the middle ear.

Opening of Tensor Tympani Canal,—the tensor tympani muscle.

Glaserian Fissure,—laxator tympani muscle, tympanic artery; lodges the processus gracilis of the malleus.

Carotid Foramen (19),—internal carotid artery, nerves from the superior cervical ganglion to the carotid plexus.

Anterior Condyloid Foramen, - see above, under Posterior Fossa.

Foramen Lacerum Posterius (20),—see above, under Posterior Fossa.

Orifice of the Canal of Hugier,—chorda tympani nerve.

 Foramen for Jacobson's Nerve,—tympanic branch of the glosso-pharyngeal.

Foramen jor Arnold's Nerve,—auricular branch of the pneumogastric.

Opening of the Aquæductus Cochleæ,—artery and vein to the cochlea.

Stylo-mastoid Foramen (18),—facial nerve, stylo-mastoid artery.

Auricular Fissure,—exit of Arnold's nerve.

Posterior Condyloid Foramen, - see above, under Posterior Fossa.

Foramen Magnum (23),—see above, under Posterior Fossa.

Face presents 4 pairs, viz.—

Supraorbital Foramen or Notch,—supraorbital artery, vein, and nerve.

Infraorbital Foramen, -infraorbital artery, vein, and nerve.

Orifice of the Anterior Naris, -air to the lungs.

Mental Foramen,-mental nerve and artery.

# POINTS AT THE BASE OF THE SKULL,

illustrated and numbered on fig. 25.

Median Suture (1),—of the palatine vault, crucial in form below.

Posterior Nasal Spine (4),—the posterior border of the palatine vault.

Vomer (5),—or nasal septum, its posterior border.

Hamular Process (6),—of the pterygoid process of the sphenoid bone.

Internal Plate (7),—of the pterygoid process of the sphenoid bone.

External Plate (8),—of the pterygoid process of the sphenoid bone.

Scaphoid Fossa (9),—on the internal plate (7) of the pterygoid process.

Zygoma (13),—or zygomatic process of the temporal bone.

Basilar Suture (14),—between the occipital and sphenoid bones.

Basilar Process (22),—of the occipital bone.

Glenoid Fossa (15),—containing the Glaserian fissure.

External Auditory Meatus (16),—opening of the ext. auditory canal.

Mastoid Process (17),—of the temporal bone.

Styloid Process (18),—of the temporal bone.

Occipital Condyles (21),—articulate with the atlas.

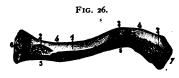

External Occipital Crest (24),—terminating at the protuberance. Inferior Curved Lines (25),—of the occipital bone.

# BONES OF THE UPPER EXTREMITY.

### THE SHOULDER.

Bones forming the Shoulder are the clavicle and scapula connecting the arm with the trunk, and in this respect homologous to the innominate bone in the lower part of the body, being sometimes called the *shoulder girdle*, as the innominate bones are called the *pelvic girdle*.

The Clavicle, collar- or key-bone, is a short bone by structure, having no medullary canal It is curved like the letter f, its inner two-thirds being

cylindrical, and convex anteriorly; its outer third flattened, and concave anteriorly. It is placed horizontally between the sternum and the scapula and is the most elastic bone in the body. It presents, from within outward, the following points, viz.—

Facets (6),—for articulation with the sternum and the cartilage of the 1st rib, at its sternal end.

Impression (2),—for the rhomboid, or costo-clavicular ligament.

Groove (1),—on the lower surface, for the subclavius muscle.

Tubercle,—for the conoid part of the costo-clavicular ligament.

Oblique Line,—for the trapezoid part of the same ligament.

Facet (7),—on the acromial end, for articulation with the scapula.

Nutrient Foramen,—in the subclavian groove.

The Scapula, or shoulder-blade, is a large, flat, and triangular bone, situated on the posterior and lateral portion of the thorax, from the 2d rib to the 7th, inclusive. Its—

VENTER, or anterior surface, presents from within outward,—

Ridges,—giving attachment to the subscapularis muscle.

Marginal Surface,—along the inner border, for the attachmen\* of the serratus magnus muscle.

Subscapular Fossa, and Angle,—for the subscapularis muscle.

DORSUM, or posterior surface, presents the following, viz.—

Spine (10),—a bony ridge, which affords attachment to the trapezius and deltoid muscles, and ends in the acromion process.

Supraspinous Fossa (1),—above the spine, for the supraspinatus muscle. Infraspinous Fossa (2),—below the spine, larger than the supraspinous,

convex at its centre, lodges the infraspinatus muscle, and the nutrient foramen.

Marginal Surjace,—along the external border, to which are attached the

teres minor muscle above, the teres major below, and sometimes a few fibres of the latissimus dorsi at the lower angle.

Groove,—crossing the margin, for the dorsalis scapulæ vessels.

Smooth Surface (11),—behind the root of the spine, over which the trapezius muscle glides.

ACROMION PROCESS (12), or summit of the shoulder, extends from the spine, and projects over the glenoid cavity, articulating with the clavicle by an oval facet. It affords attachment to the deltoid and trapezius muscles, and by its apex to the coraco-acromial ligament.

CORACOID PROCESS (14), or crow's beak, projects from the upper border

and neck of the bone over the inner and upper part of the glenoid cavity. Into it is inserted 1 muscle, the pectoralis minor; the coraco-brachialis and the short head of the biceps arise from it by a common tendon, and 3 ligaments are attached to it,—the conoid, trapezoid, and coraco-acromial.

SUPERIOR BORDER (3) presents the-

Suprascapular Notch (4),—converted into a foramen for the suprascapular nerve by the transverse ligament, over which passes the suprascapular artery. The omo-hyoid muscle is attached to the border just internal to this notch.

AXILLARY BORDER (5) is the thickest, and presents a-

Rough Surjace (8),—for the long head of the triceps muscle, just below the glenoid cavity.

Groove,—the origin of a part of the subscapularis muscle.

VERTEBRAL BORDER (9) is the longest, and presents an-

Anterior Lip,—for the attachment of the serratus magnus.

Posterior Lip,—for the supra- and infra-spinatus muscles.

Interspace,—between the lips, for the levator anguli scapulæ, the rhomboideus minor, and the fibrous arch of the rhomboideus major muscles. OTHER POINTS of interest on the bone are the-

Superior Angle,—affords attachment to part of the serratus magnus, levator anguli scapulæ, and supra-spinatus muscles.

Injerior Angle (7),—affords attachment to part of the serratus magnus and teres major muscles, and to a few fibres of the latissimus dorsi.

Glenoid Cavity (6),—at the external angle or head of the bone, a shallow cavity for the reception of the head of the humerus. It is deepened by the glenoid ligament which is attached around its margin; and gives origin to the long head of the biceps flexor cubiti muscle.

Neck,—is the contracted part of the bone behind the glenoid cavity; from it arises the anterior root of the coracoid process.

### THE ARM.

The Humerus is the only bone in the arm, and articulates with the scapula above, and with the ulna and radius below. It presents for examination a shaft and two extremities, on which are the following FIG. 28. points, viz.-

Head (b),—is nearly hemispherical, and smooth for articulation with the glenoid cavity of the scapula.

Anatomical Neck (c),—is a constriction in the bone, just below the head, for the attachment of the capsular ligament.

Greater Tuberosity (d),—has 3 small facets for the insertions of the supraspinatus, infraspinatus, and teres minor muscles.

Lesser Tuberosity (e),—on the inner side of the bone, gives insertion to the subscapularis muscle.

Bicipital Groove (f),—lies vertically between the tuberosities for the upper third of the bone, and lodges the tendon of the long head of the biceps flexor cubiti. Into its inner or posterior lip (h) are inserted the teres major and latissimus dorsi muscles, while its outer or anterior lip (g) receives the insertion of the tendon of the pectoralis major, which covers the groove.

Surgical Neck,—is situated immediately below the tuberosities, and is a slight constriction in the upper part of the shaft

Shaft (a),—is cylindrical above, prismatic and flattened below.

Rough Surface (i),—for the insertion of the deltoid muscle, about the middle of the external surface of the shaft.

- Musculo-spiral Groove (a),—lodging the musculo-spiral nerve and the superior profunda artery, is situated on the posterior surface of the shaft. separating the origins of the outer and inner heads of the triceps muscle.
- Orifice (j)—of the nutrient canal, about the middle of the shaft, on its internal border.
- Condyloid Ridges —internal (p) and external (o), arising from the respective condyles, extending upward along the shaft.
- External Condyle (m),—gives attachment to the external lateral ligament and the extensor and supinator group of muscles.
- Internal Condyle (n),—lower and more prominent than the other, gives attachment to the internal lateral ligament and the flexor and pronator group of muscles of the fore-arm.
- Radial Head (k),—forms the external part of the inferior articular surface; for articulation with the radius.
- Trochlear Surface (l),—articulates with the greater sigmoid cavity of the ulna; is a deep depression between two borders, and extends from the anterior to the posterior surface of the bone.
- Coronoid Fossa,—above the front of the trochlear surface, receives the coronoid process of the ulna when the fore-arm is flexed.
- Olecranon Fossa (q),—above the back part of the trochlea, receives the tip of the olecranon process, when the fore-arm is extended.

#### THE FORE-ARM.

The skeleton of the fore-arm is composed of 2 bones, parallel with each other, the *ulna* internally and the *radius* externally.

The Ulna, or elbow-bone, is the internal bone of the fore-arm. It is larger and longer than the radius, forming the greater portion of the articulation with the humerus. It does not enter into the formation of the wrist-joint, being excluded therefrom by an interarticular fibro-cartilage. It presents for examination a shaft and two extremities, on which are the following points:—

- Olecranon Process (4),—at the upper extremity, forming the elbow. It is curved forward, its apex being received into the olecranon fossa of the humerus when the fore-arm is extended. Its posterior surface gives insertion to the tendon of the triceps. In its function and structure it resembles the patella.
- Coronoid Process (5),—below the olecranon, projects forward, its apex being received into the coronoid fossa of the humerus when the fore-arm is flexed. Its upper surface is concave for articulation with the humerus, its lower surface rough for the insertion of the brachialis anticus muscle. Its inner surface has a margin for the internal lateral ligament, a tubercle

for the flexor sublimis digitorum, and a ridge for the pronator radii teres.

Greater Sigmoid Cavity (2),—lies between the processes, and is divided by a vertical ridge into two unequal parts. It articulates Fig. 29. with the trochlear surface of the humerus.

(h)

Lesser Sigmoid Cavity (3),—lies external to the coronoid process; is oval and concave, articulating with the head of the radius, and giving attachment to the orbicular ligament.

Shaft (1),—large and prismatic above, smaller and rounded below, has the Nutrient Foramen (6) on its anterior surface (1), and a prominent margin externally, to which is attached the interosseous membrane (7). It gives attachment to 9 of the 12 muscles of the fore-arm.

Head (8),—at the carpal end, articulates with the lesser 'sigmoid cavity of the radius, and the fibro-cartilage of the wrist-joint.

Styloid Process (9),—projecting from the head internally and posteriorly, its apex gives attachment to the internal lateral ligament, and a depression at its root to the fibro-cartilage of the joint.

Groove,—for the tendon of the extensor carpi ulnaris muscle.

The Radius lies externally to the ulna when the forearm is in supination; it is prismatic in form with the base

below where it articulates with the carpus. The bone is curved outward and is shorter than the ulna, by the length of the olecranon. It presents the following points from above downward, viz.—

Head (11),—cylindrical and cup-shaped, articulating with the radial head of the humerus, and the lesser sigmoid cavity of the ulna, and playing within the orbicular ligament.

Neck (12),—the constricted part below the head.

Bicipital Tuberosity (13),—rough behind for the insertion of the bicers, and smooth in front where it is covered by a bursa.

Shaft (10),—prismoid in form, presents a sharp border internally for the attachment of the interosseous membrane; the Nutrient Foramen is on its anterior surface. It gives attachment to 8 of the 12 muscles of the fore-arm.

Ridge (14),—for the insertion of the pronator radii teres muscle.

Sigmoid Cavity,—at the internal side of the carpal end (15), is shallow, and articulates with the head of the ulna.

Articular Surface,—is divided by a ridge into 2 facets for articulation with the semilunar and scaphoid bones of the carpus.

Styloid Process (16),—externally, gives attachment by its apex to the external lateral ligament, and by its base to the supinator longus muscle.

Grooves,—on the posterior and external surfaces of the lower extremity, for the tendons of the 8 extensor muscles of the thumb, and those of the radial side of the wrist, and fingers.

### THE HAND.

The Bones of the Hand are divided into the carpus 8, the metacarpus 5, and the phalanges 14. Total, 27 bones.

Bones of the Carpus. The 8 bones are placed in 2 rows, one row in front of the other, with 4 bones in each row, as follows,—the right hand being in supination, naming from without inward, viz.—

1st, or Proximal Row,—Scaphoid (s), Semilunar (L), Cuneiform (c), Pisiform (P).

2d, or Distal Row, — Trapezium (τ), Trapezoid (τ), Os-magnum (M), Unciform (U).

Articulations in the Carpus are 34, as follows;—the number after each bone representing the number of its articulations, viz.—

Scaphoid, 5. Semilunar, 5. Cuneiform, 3. Pisiform, 1. Trapezium, 4. Trapezoid, 4. Os-magnum, 7. Unciform, 5.

Peculiarities of the Carpal Bones. The first three enter into the formation of the wrist-joint; the pisiform does not, but is wholly without it, and may be considered a mere appendage of the carpus. When the hand is in pronation—

The Scaphoid, or boat-shaped bone (S)—has a tuberosity on its outer side, its largest facet is uppermost and articulates with the lower end of the radius (R). A transverse groove crosses its posterior surface and serves for the attachment of ligaments.

The Semilunar Bone (L)—has a crescentic facet externally, and a convex facet superiorly, where it articulates with the radius.

- The Currenform Bone (C)—is wedge-shaped, its convex surface above, articularing with the interarticular fibro-cartilage of the wrist (F). It has an oval facet anteriorly for articulation with the pisiform.
- The Pisiform Bone (P)—is the smallest, and has but one facet, which lies posteriorly when the bone is in position.
- The Trapezium (T)—has a deep groove for the tendon of the flexor carpi radialis, and a saddle-shaped facet, inferiorly, for the base of the 1st metacarpal.
- The Trapezoid (T)—is small and quadrilateral, bent on itself, with a saddle-shaped facet looking downward, for the base of the 2d metacarpal bone.
- The Os-magnum (M)—has a head looking upward, a neck, and a body; is the largest bone of the carpus, and has 3 facets on the inferior surface for articulation with the 2d, 3d, and 4th metacarpal bones.
- The Unciform Bone (U)—is wedge-shaped, with a concavity which lies to the outer side, and the unciform process, long and curved, projecting from its palmar surface.

The Metacarpus consists of the 5 metacarpal bones which are placed between the carpus and the phalanges. They are long bones, and each has a head, shaft and base. Their heads articulate with the respective phalanges.

- 1st Metacarpal Bone (1),—articulates with the trapezium, is shorter than the others by one-third, and its base has but 1 articular facet. This bone was classed among the phalanges by Professor W. H. Pancoast.
- 2d Metacarpal Bone (2),—articulates with 3 bones of the carpus, the trapezium, trapezoid, and os-magnum; its base is large, and has 4 articular facets.
- 3d Metacarpal Bone (3),—articulates with 1 bone of the carpus, the osmagnum; its base has a projecting process on the radial side, and 2 small facets on the opposite side.
- 4th Metacarpal Bone (4),—articulates with 2 bones of the carpus and with the adjacent metacarpal bones; its base is small and has 2 circular facets 1 on each side.
- 5th Metacarpal Bone (5),—articulates with 1 carpal bone, the unciform its base has 1 lateral articular facet.

The Phalanges or finger-bones, are 14 in number (15 according to Pancoast), 3 to each finger, and 2 to the thumb. They are long bones, and each has a base, a shaft, and a digital extremity. The Bases of the first row articulate with the heads of the metacarpal bones. The Digital Extremities of the first and second rows have each 2 small lateral condyles, while in the terminal row they are rough, for the attachment of the sensitive pulp of the fingers.

### BONES OF THE LOWER EXTREMITY.

The bones of the lower extremity consist of those of the pelvic girdle, of the thigh, of the leg and of the foot.

The Pelvic Girdle consists of a single bone, the os innominatum, by which the thigh is connected to the trunk. It is described on page 18, among the bones of the pelvis.

### THE THIGH.

The Femur or thigh-bone, is the longest, largest and strongest bone in the

body, and is nearly cylindrical in the greater part of its extent. In the vertical position of the skeleton it forms one side of a triangle, of which the base is the breadth of the pelvis, and the apex at the knee-joints. The base of this triangle is longest in the female, and consequently that sex is usually knock-kneed. The—

Head (5),—articulates with the acetabulum, forms about two-fifths of a sphere, and has an oval depression (6) below its centre for the attachment of the ligamentum teres.

Neck (7),—connects the head with the shaft, is pyramidal and flattened; its obliquity varies with age, being less before puberty, about 120 to 125 degrees in the adult, and nearly horizontal to the shaft in old or debilitated subjects.

Great Trochanter (8),—a broad, rough, quadrilateral process directed outward and backward from the summit of the shaft to within three-fourths of an inch of the level of the head. On its outer surface the tendon of the gluteus maximus plays over a bursa. It gives insertion to the obturator internus, two gemelli, pyriformis, and gluteus minimus and medius muscles.

Digital Fossa (9),—on the inner surface of the great trochanter, gives insertion to the obturator externus muscle.

Lesser Trochanter (10),—at the inferior root of the neck posteriorly, is small and conical, and affords insertion to the

- tendon of the psoas magnus muscle, the tendon of the iliacus being inserted immediately below it.
- Inter-trochanteric Lines,—anterior and posterior, the latter the most prominent; to the anterior is attached the capsular ligament of the hip-joint.
- Linea Quadrati,—extends from the middle of the posterior inter-trochanteric line about 2 inches down the shaft, and gives attachment to the quadratus femoris muscle.
- Shaft,—is slightly curved forward, broad and cylindrical at each end, and narrow and triangular in the centre. Its nutrient foramen perforates its posterior surface below the centre. From its anterior surface arise the crureus and sub-crureus muscles.
- Linea Aspera (1),—a crest lying along the central third of the shaft posteriorly; bifurcating above (2) towards each trochanter, also below (4) towards the 2 condyles. To its outer lip is attached the vastus externus, to its inner lip, the vastus internus; and between them, the pectineus, adductor brevis, and gluteus maximus above the short head of the biceps below, and the adductors longus and magnus along the greater portion of the space.
- Groove,—crossing the internal condyloid ridge, lodges the femoral artery Popliteal Space,—triangular and smooth, lying between the condyloid ridges, for the popliteal artery.
- External Condyle (11),—broader and shorter than the internal, so as to form a horizontal articulation, the bone being inclined towards the median line. It gives attachment to the external lateral ligament, and the popliteus and gastrocnemius muscles.
- Internal Condyle (12),—the longest by half an inch; it gives attachment to the internal lateral ligament and the gastrocnemius muscle.
- Intercondyloid Notch (13),—lodges the crucial ligaments. In front the condyles are continuous with each other, forming a concave depression or trochlea for the patella.
- Outer Tuberosity (14),—on the external condyle, for the attachment of the external lateral ligament.
- Groove,—below the outer tuberosity, for the tendon of the popliteus muscle, terminating in a depression whence the muscle takes its origin.
- Inner Tuberosity (15),—on the internal condyle, for the attachment of the internal lateral ligament.
- Tubercle,—above the inner tuberosity, for the insertion of the tendon of the adductor magnus muscle.
- Depression,—behind the tubercle, for the tendon of the inner head of the gastrocnemius.

### THE LEG.

The skeleton of the leg consists of 3 bones, the *tibia*, the *fibula* and the *patella*, the latter being a large, sesamoid bone placed in front of the knee.

The Tibia, or shin-bone, ranks next to the femur in respect to size and length. Its form is prismoidal, the upper extremity being much larger than the lower. It presents the following points:—

Head,—expands into two lateral tuberosities, internal (2) and external (3) which articulate with the condyles of the femur.

Spine (4),—projects vertically between the 2 articular surfaces, is bifid,

affording attachment to the semilunar fibro-cartilages, and by depressions in front and behind its base to the crucial ligaments of the joint.

Tubercle (5),—on the head, anteriorly between the tuberosities, for the insertion of the ligamentum patellæ.

Popliteal Notch,—posteriorly between the tuberosities, affords attachment to the posterior crucial ligament.

Groove,—on the inner tuberosity (2) posteriorly, for the insertion of the tendon of the semi-membranosus muscle.

Facet,—on the outer tuberosity (3) posteriorly and looking downward, for articulation with the head of the fibula.

Popliteal Line,—obliquely across the upper part of the shaft posteriorly, affords attachment to the fascia of the popliteus, and parts of the soleus, flexor longus digitorum, and tibialis posticus muscles.

Nutrient Canal,—the largest in the skeleton, opens just below the popliteal line, its orifice looking upward.

Shaft (1),—has 3 sharp ridges,—I in front, the Crest (6) or Shin, and I on either side, to the external of which is attached the interosseous membrane.

Lower Extremity (7),—is smaller than the upper, grooved posteriorly for the tendon of the flexor longus pollicis; externally has a rough triangular depression for articulation with the fibula, and for the attachment of the

inferior interosseous ligament. Its inferior surface is concave and smooth for articulation with the upper surface of the astragalus.

Internal Malleolus (8),—projects downward from the internal side of the lower extremity. It articulates with the astragalus, is grooved poste-

riorly for the tendons of the tibialis posticus and flexor longus digitorum muscles, and affords attachment to the internal lateral ligament.

The Fibula, is a long slender bone, placed nearly parallel with the tibia on the outer side of the leg. It is also called the *Peroneus*, or peroneal bone.

- Head (10),—articulates with the external tuberosity of the tibia by a flat facet. Externally it has a prominence for the attachment of the long external lateral ligament of the knee-joint.
- Styloid Process,—projects upward from the head posteriorly, and gives insertion to the tendon of the biceps muscle, and the short external lateral ligament of the knee-joint.
- Shaft (9)—is triangular and twisted on itself, having 3 marked ridges, the innermost of which is sharp for the attachment of the interesseous membrane. The shaft arches backward, and gives attachment to 8 of the 12 muscles of the leg.
- Nutrient Canal,—opens about the centre of the shaft posteriorly, its orifice looking downward.
- External Malleolus (11),—is the lower extremity of the bone. It is larger and longer than the internal, articulates with the astragalus by a triangular facet, and is grooved posteriorly for the tendons of the peroneus longus and peroneus brevis muscles. Its edge affords attachment to the external lateral ligament of the ankle-joint.

#### THE FOOT.

The Bones of the Foot are divided into those of the tarsus 7, metatarsus 5, and phalanges 14. Total, 26 bones.

Bones of the Tarsus are placed in 2 rows side by side, 2 bones in the external row, 5 in the internal, as follows, viz.—

Internally,— Astragalus (5). Scaphoid (8). 3 Cuneiform (10, 11, 12). Externally,— Os calcis (1), or Calcaneum. Cuboid (6).

[The illustration, Fig. 33, shows the plantar surface of the skeleton of the foot.]

Articulations in the Tarsus are 28 in number, each bone articulating with 4 others, except the os calcis, which articulates with 2, and the external cuneiform with 6 bones.

Peculiarities of the Tarsal Bones. They may be divided transversely at the astragalo-scaphoid-calcaneo-cuboid articulation, the site of Chopart's operation. The—

Astragalus (5),—has a rounded head, a convex surface on which is a broad

articular facet, and on its inferior surface a deep groove between 2 articular facets.

Os Calcis (1),—is a large bone, having on its upper surface a deep groove for the interosseous ligament, between 2 articular surfaces; anteriorly a large irregular portion, the head; and posteriorly an elongated portion

forming the Heel 2). On its internal surface is a projection, the Sustentaculum Tali, which supports the internal articulating surface; below which process the bone is deeply grooved for the plantar vessels and nerves and the flexor tendons. To the os calcis are attached 8 muscles and the plantar fascia.

Navicular or Scaphoid Bone (8),—is boatshaped, has 3 facets anteriorly for the cuneiform bones, a concave surface posteriory for the astragalus, and a facet externally for the cuboid bone. A tubercle (9) is situated on the lower surface internally, for the insertion of the tibialis posticus muscle.

Cuboid Bone (6),—has 3 articular surfaces, and a groove inferiorly for the tendon of the peroneus longus.

Internal Cuneijorm Bone (10), the largest of the 3, has a tubercle on its plantar surface for the insertion of parts of the tendons of the tibialis anticus and tibialis posticus muscles.

Middle Cuneiform Bone (11),—is small and

wedge-shaped with the narrow end downward. Its anterior surface is considerably behind the line of the tarso-metatarsal articulation, thus forming a recess into which the base of the second metatarsal bone fits. External Cuneiform Bone (12),—is also wedge-shaped, but longer than the middle one; and affords origin to 1 muscle, the flexor brevis pollicis.

The Metatarsus consists of 5 metatarsal bones, which are long bones, having each a shaft and two extremities. Their bases articulate with the tarsal bones and with each other; their heads with the first row of phalanges.

1st Metatarsal (13),—is large but shorter than the others, and forms the inner border of the foot, articulating with the internal cuneiform. The

head is large and has two grooved facets on its plantar surface, over which glide 2 sesamoid bones (19).

- 2d Metatarsal (14),—is the longest; its base has 3 facets for articulation with the 3 cuneiform bones in the recess formed by the shortness of the middle cuneiform.
- 3d Metatarsal (15),—has 2 facets on the inner side of its base, besides the facets for the internal cuneiform and the 4th metatarsal bone.
- 4th Metatarsal (16),—articulates with the cuboid bone, and also with the internal cuneiform.
- 5th Metatarsal (17),—articulates obliquely with the cuboid bone, and has a tubercular projection (18) on the outer surface of its base, which forms the guide to Hey's operation.

The Phalanges of the Foot number 14 as in the hand, the great toe having two (20, 21), the other toes three each. They are long bones, each having a base, a shaft, and an anterior extremity. They are convex above, concave below, and articulate by the bases of the first row with the bones of the metatarsus. The anterior extremities of the distal phalanges (21, 23) are expanded into surfaces for the support of the nails and pulp of the toes.

### THE ARTICULATIONS.

An Articulation or Joint is a connection between two bones of the skeleton, and has entering into its formation the following-named structures,—bone, cartilage, fibro-cartilage, ligament and synovial membrane.

Articulations are divided into three classes,—Synarthrosis, immovable joint; Amphiarthrosis, mixed articulation, having limited motion; and Diarthrosis, movable joint, having free motion.

Synarthroses are subdivided into—Sutura, formed by processes and indentations; Schindy'lesis, by a plate of bone entering into a fissure of another; and Gompho'sis, by a conical process into a socket. The Sutura are again subdivided into—S. dentata, having tooth-like processes; S. serrata, with serrated edges; S. limbosa, having beveled margins and dentated processes; S. squamosa, with thin beveled margins overlapping each other; S. harmonia, contiguous rough surfaces opposed to each other. The first 3 are also named Sutura Vera (true sutures) having indented borders; the last 2 Sutura Notha (false sutures) being formed by rough surfaces.

Amphiarthroses are subdivided into—Symphysis, connected by fibrocartilage and not separated by synovial membrane; Syndesmosis, united by an interosseous ligament.

Diarthroses are subdivided into—Ginglymus, hinge-joint; Trochoides, pivot-joint, formed by a ring surrounding a pivot; Condyloid, by an ovoid head in an elliptical cavity; Reciprocal Reception, saddle-joint, by surfaces inversely convex and concave; Enarthrosis, ball-and-socket joint; Arthrodia, gliding joint.

## Examples of each of the above-named articulations, as follows;—

Synarthrosis, -- joints of the cranium and face, except the lower jaw.

Sutura Dentata,-the inter-parietal suture.

Sutura Serrata,—the inter-frontal suture.

Sutura Limbosa,—the fronto-parietal suture.

Sutura Squamosa,—the temporo-parietal suture.

Sutura Harmonia,—the intermaxillary suture.

Schindylesis,-rostrum of sphenoid with the vomer.

Gomphosis,—the teeth in their alveoli.

Amphiarthrosis,—the joints between the bodies of the vertebræ (symphyses); the inferior tibio-fibular articulation (syndesmosis).

Diarthrosis, movable joint, as follows:-

Ginglymus,—inter-pharyngeal joints and the elbow-joint.

Trochoides, - superior radio-ulnar, atlanto-axial joint.

Condyloid,—the wrist-joint.

Reciprocal Reception,—the carpo-metacarpal joint of the thumb.

Enarthrosis,—the hip- and shoulder-joints.

Arthrodia,—the carpal and tarsal articulations.

Varieties of Motion in Joints are 4 in number, viz.—gliding, angular movement (including adduction, abduction, flexion and extension), circumduction and rotation. These movements are often more or less combined in the various joints.

Structures entering into the formation of Joints are 5, viz.,—the articular lamella of bone, cartilage, fibro-cartilage, ligaments and synovial membrane.

Articular Lamella of Bone—differs from ordinary bone tissue in being more dense, containing no Haversian canals nor canaliculi, and having larger lacunge.

Cartilage,—a non-vascular structure, is divisible into temporary and permanent varieties. The first forms the original frame-work of the skeleton, and becomes ossified. Permanent cartilage is not prone to ossification, and is divided into 4 groups,—Articular, covering the ends of bones in joints; Interarticular, between the bones in a joint; Costal, forming part of the skeleton; and Membranijorm. According to its

minute structure, cartilage is divided into Hyaline Cartilage, White Fibro-cartilage and Yellow or Elastic Fibro-cartilage.

Fibro-cartilages,—in joints and osseous grooves are of the white variety and may be arranged in 4 groups, the—Interarticular (menisci), separating the bones of a joint; Connecting, binding bones together; Circum
ferential, deepening cavities; Stratiform, lining grooves.

Ligaments—are bands of white fibrous tissue, except the ligamenta subflava and the ligamentum nuchæ, which consist entirely of yellow elastic tissue.

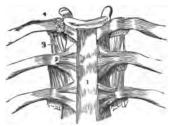

Synovial Membranes—secrete the synovia, a viscid, glairy fluid, and resemble the serous membranes in structure. They are Articular, lubricating joints; Bursal, forming closed sacs (bursæ) interposed between surfaces which move upon each other; Vaginal, ensheathing tendons.

### ARTICULATIONS OF THE TRUNK.

The Vertebral Articulations are formed by the adjacent surfaces of the bodies of the vertebræ and their processes, and are connected by the following ligaments, etc.—

Anterior Common Ligament (1),—along the fronts of the bodies.

FIG. 34.

Posterior Common Ligament,—along the backs of the bodies.

Ligamenta Subflava,—connect the laminæ of adjacent vertebræ.

Capsular (4),—surround the articular processes and are lined by synovial membrane.

Supra-spinous and Inter-spinous, connect the spinous processes.

Inter-transverse (3),—connect the transverse processes.

Intervertebral Substance,—in lentic-

ular disks between the bodies of the vertebræ, from the axis to the sacrum.

The Atlanto-axial Articulation is a double arthrodia or gliding joint between the articular processes and a double pivot articulation between the atlas and the odontoid process. It has 6 ligaments and 4 synovial membranes, as follows:—

Anterior 2, and Posterior 1, Atlanto-axial,—continuations of the anterior and posterior common spinal ligaments.

Capsular 2,—surrounding the articular surfaces, each lined by a synovial membrane.

Transverse Ligament,—divides the spinal foramen of the atlas into two portions, stretching across between the tubercles on the inner sides of the articular processes. It holds the odontoid process in place, having a synovial membrane interposed. Another synovial membrane is situated between the process and the anterior arch. The transverse ligament sends two vertical slips, one upward, the other downward, from which it is often named the Cruciform Ligament.

The Occipito-antal Articulation is a double condyloid formed by the

condyles of the occipital bone with the superior articular surfaces of the atlas, and has 6 ligaments, viz.—

Anterior Occipito-atlantal (a),—from the anterior margin of the foramen magnum to the anterior arch of the atlas.

Posterior Occipito-atlantal,—from the posterior margin of the foramen magnum to the posterior arch of the atlas. It is perforated by the vertebral and suboccipital nerves.

Lateral 2,—from the jugular processes

of the occipital bone to the bases of the transverse processes of the atlas.

Capsular 2 (d),—around the articular surfaces, lined by synovial membrane.

The Occipito-axial Articulation is formed by the occipital bone and the odontoid process of the axis, which do not articulate with each other strictly, but are connected with 4 ligaments, the—

Occipito-axial (1) (Apparatus Ligamentosus Colli),—a continuation of the posterior common spinal ligament to the basilar process of the occipital bone.

Lateral Occipito-odontoid (5) (Check Ligaments) 2,—from the head of the odontoid process to the inner sides of the occipital condyles.

Middle Odontoid (Ligamentum Suspensorium),—from the anterior margin of the foramen magnum to the odontoid apex.

The Temporo-mandibular Articulation is a ginglymo-arthrodial joint between the condyle of the lower jaw and the anterior part of the glenoid cavity of the temporal bone. It has 2 synovial membranes with an interarticular fibro-cartilage between them, and 4 ligaments, viz.—

FIG. 35.

External Lateral,—from the tubercle of the zygoma to the outer side of the neck of the condyle of the lower jaw.

FIG. 36.

Internal Lateral (d),—from the spine of the sphenoid to the margin of the dental foramen.

Stylo-mandibular (f),—from the styloid process of the temporal bone to the angle and posterior border of the ramus of the lower jaw.

Capsular (c),—from the edge of the glenoid cavity and the eminentia articularis to the neck of the condyle of the lower jaw.

Its Nerves are derived from the auriculotemporal and masseteric branches of the

inferior maxillary. Arteries from the temporal branch of the external carotid.

The Costo-vertebral Articulations are each a double arthrodia between the head of the rib and the bodies of 2 adjacent vertebræ, except in the 1st, 1oth, 11th, and 12th ribs, which are each a single arthrodia, as they articulate with but 1 vertebra each. Their ligaments are 3, viz.—

Anterior Costo-vertebral (2), or Stellate Ligament,—consists of 3 bundles, which fasten the anterior part of the head of the rib to the intervertebral disk and the 2 adjacent bodies.

Inter-articular,—in the interior of the joint, from the crest on the head of the rib to the intervertebral disk; on each side there is a separate synovial membrane. In the 1st, 1oth, 11th and 12th ribs it does not exist, hence there is but one synovial membrane.

Capsular,—surrounding the articular surfaces.

The Costo-transverse Articulations are 10 arthrodial articulations between the tubercles of the first 10 ribs and the transverse processes of the vertebræ next below. Their ligaments are 4, viz.—Anterior, Middle (interosseous) and Posterior Costo-transverse.

The Chondro-sternal Articulations are 7 in number, 1 of which (the first) is a synarthrodial and 6 are arthrodial articulations, between the costal cartilages and the margin of the sternum. The first has no synovial membrane, the second only has an inter-articular fibro-cartilage. Each has 4 ligaments,—the Anterior and Posterior Chondro-sternal, a Capsular, and an Interarticular. The Chondro-xiphoid Ligaments connect the xiphoid appendix to the cartilage of the 6th or 7th rib.

The Costo-chondral and Interchondral Articulations connect the

costal cartilages with the ribs and with each other respectively. With the ribs by a depression on the end of each rib, strengthened by the blending together of the periosteum and the perichondrium. The 6th, 7th and 8th, and sometimes the oth and 10th costal cartilages articulate with each other by their borders and each has a Capsular and an Interchondral ligament, with 3 synovial membranes for the 3 articulations between the 6th and the 9th cartilages.

The Ligaments of the Sternum are an Anterior Sternal and a Posterici Sternal ligament, with a layer of cartilage between the manubrium and th. gladiolus.

The Sacro-vertebral Articulation is similar to the other vertebral articulations, but has 2 additional ligaments on each side, the-

Lumbo-sacral,—from the transverse process of the 5th lumbar vertebra to the base of the sacrum laterally and anteriorly.

Ilio-lumbar,—from the apex of the transverse processes of the 5th lumbar vertebra to the crest of the ilium in front of the sacro-iliac articulation.

The Sacro-coccygeal Articulation is an amphiarthrodial joint, and has 4 ligaments, viz.-

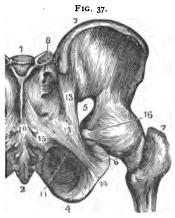

Anterior Sacro-coccygeal. Posterior Sacro-coccygeal.

Lateral Sacro-coccygeal. Interarticular. Fibro-cartilage, interposed in the joint.

The Sacro-iliac Articulation is an amphiarthrodial joint, formed by the lateral surfaces of the sacrum and ilium. Its ligaments on each side are the-

> Anterior Sacro-iliac. Posterior Sacro-iliac (8). Oblique Sacro-iliac.

The Sacro-ischiatic Articulation is an amphiarthrosis between the sacrum and the ischium. Its ligaments convert the sacro-sciatic notches into foramina, the greater notch (5) being crossed by the lesser ligament, the lesser notch (6) by the greater ligament. These foramina are described on page 19 ante.

Great Sacro-sciatic Ligament (13),—from the posterior inferior spine of the

ilium and the posterior surfaces and margins of the sacrum and coccyx (2), to the inner margin of the tuberosity (4) and the ascending ramus (14) of the ischium, the latter portion being known as the Falcijorm Ligament.

Lesser Sacro-sciatic Ligament (15),—from the margins of the sacrum and coccyx, into the spine of the ischium (16).

The Pubic Articulation or Symphysis Pubis, is an amphiarthrodial joint formed by the junction of the two pubic bones with each other. It has an interpubic disk and 4 ligaments, the—

Anterior Pubic. Posterior Pubic. Superior Pubic. Sub-pubic, forming a fibrous arch between the rami.

### ARTICULATIONS OF THE UPPER EXTREMITY.

The Sterno-clavicular Articulation is an arthrodial joint, formed by the sternal end of the clavicle with the sternum and the cartilage of the 1st rib. It has an interarticular fibro-cartilage, 2 synovial membranes and 5 ligaments, the—

Anterior Sterno-clavicular. Interclavicular.

Posterior Sterno-clavicular. Costo-clavicular or Rhomboid.
Capsular.

The Acromio-clavicular Articulation is an arthrodial joint, formed by the outer extremity of the clavicle and the acromion process of the scapula. It frequently has an interarticular fibro-cartilage and 2 synovial membranes (usually but 1 is present). It has 3 ligaments, the—

Superior Acromio-clavicular(1). Coraco-clavicular (2) Trapezoid, externally.

Inferior Acromio-clavicular. divided into— Conoid, internally.

Proper Ligaments of the Scapula are 2, the Coraco-acromial, and the Transverse, as follows:—

Coraco-acromial (3),—completes the vault partially formed by the coracoid and acromion processes over the head of the humerus.

Transverse (4),—from the base of the coracoid process to the margin of the suprascapular notch, converting it into a foramen for the suprascapular nerve.

The Shoulder-joint is an enarthrodial or ball-and-socket joint, formed by the head of the humerus and the glenoid cavity of the scapula. It has a Synovial Membrane which is reflected upon the tendons of the biceps, subscapularis, and infraspinatus muscles, and communicates with bursæ beneath the 2 latter tendons. Its Arteries are derived from the anterior and

posterior circumflex and the suprascapular; its Nerves from the circumflex and the suprascapular. It has 3 ligaments, the-

Capsular (5), from the margin of the glenoid cavity to the anatomical neck of the humerus; has 3 openings for the reflexions of the synovial membrane over the tendons.

Coraco-humeral (6), intimately united with the capsular, extends from the coracoid process to the greater tuberosity of the humerus.

Glenoid, a fibro-cartilaginous ring, continuous above with the tendon of the long head of the biceps (7), and attached around the margin of the glenoid cavity in order to deepen the articular surface.

> The Elbow-joint is a ginglymus or hinge articulation, formed by

FIG. 39.

the lower end of the humerus with the greater sigmoid cavity of the ulna (2) and the head of the radius (3). Its Synovial Membrane is reflected over the ligaments. and dips down between the surfaces of the superior radio-ulnar articulation. Its Arteries are derived from the anastomotica magna, brachial, radial, ulnar, and interosseous recurrent, superior and inferior profunda arteries. Its Nerves are branches of the ulnar, the musculo-cutaneous and the median. It has 4 ligaments, the-

Anterior,—from the internal condyle (7) and anterior surface of the humerus to the orbicular ligament of the radius and the coronoid process of the ulna. Posterior (6),—from the posterior surface of the humerus to the olecranon process of the ulna.

External Lateral (4),-from the external condyle of the humerus to the orbicular ligament of the radius. Internal Lateral,—from the internal condyle of the humerus (7) to the coronoid and olecranon processes of the ulna.

The Radio-ulnar Articulations are 3 in number, as follows:—

SUPERIOR RADIO-ULNAR ARTICULATION—is a trochoid or pivot-joint, formed by the head of the radius and the lesser sigmoid cavity of the ulna. Its synovial membrane is a continuation of that in the elbow-joint. It has only one ligament, the—

Orbicular Ligament (5),—forms four-fifths of a circle and surrounds the neck of the radius. It is attached to the margins of the lesser sigmoid cavity of the ulna, and to the external lateral ligament of the elbow-joint.

MIDDLE RADIO-ULNAR ARTICULATION—is formed by the shafts of the radius and ulna, which do not touch each other, but are connected by 2 ligaments, as follows;—

Oblique Ligament,—from the tubercle at the base of the coronoid process of the ulna to the shaft of the radius.

Interosseous Membrane (0),—obliquely downward from the interosseous ridge on the radius to that on the ulna. Through the interval between its upper border and the oblique ligament, the posterior interosseous vessels pass.

INFERIOR RADIO-ULNAR ARTICULATION—is a pivot-joint, formed by the head of the ulna and the sigmoid cavity of the radius. Its *Synovial Membrane* (membrana sacciformis) is very loose, and sometimes communicates with that of the wrist-joint through an opening in the triangular *fibro-cartilage* which separates the head of the ulna from the wrist-joint, and acts as one of the ligaments of this articulation, which are 3, viz.—

Anterior Radio-ulnar. Posterior Radio-ulnar Interarticular Fibro-cartilage.

The Radio-carpal Articulation, or Wrist-joint, is a condyloid articulation formed by the lower end of the radius and the triangular fibro-cartilage with the scaphoid, semilunar, and cuneiform bones of the carpus. Its Arteries are the anterior and posterior carpal from both the radial and ulnar, the anterior and posterior interosseous and ascending branches from the deep palmar arch. Its Nerves are derived from the ulnar and posterior interosseous. It is lined by a synovial membrane, and is connected by a capsule, which is divided into the following-named 4 ligaments, the—

External Lateral (radio-carpal). Anterior Ligament.

Internal Lateral (ulno-carpal). Posterior Ligament.

The Carpal Articulations are in 3 sets,—between the bones of the first row, between the bones of the second row, between the 2 rows of bones with each other.

The scaphoid, semilunar, and cuneiform bones are connected together

by Dorsal, Palmar and 2 Interosseous Ligaments. The pisiform bone has a separate capsular ligament and synovial membrane and 2 Palmar Ligaments connecting it with the unciform and the 5th metacarpal.

The 4 bones of the second row are connected together by Dorsal, Palmar and 3 Interosseous Ligaments.

The two rows of bones are united to each other by *Dorsal*, *Palmar*, and 2 *Lateral Ligaments*, the last named being continuous with the lateral ligaments of the wrist-joint.

The Carpo-metacarpal Articulations. That of the thumb with the trapezium is a joint of reciprocal reception, and has a Capsular Ligament and a separate synovial membrane. The 4 inner metacarpal bones form 4 arthrodial joints with the adjacent carpal bones by 6 Dorsal, 8 Palmar, and 2 Interosseous Ligaments, irregularly disposed.

The Synovial Membranes of the Wrist are 5 in number, and are situated as follows;—

The First, or Membrana Sacciformis,—between the head of the ulna, the sigmoid cavity of the radius, and the triangular interarticular fibrocartilage.

The Second,—between the lower end of the radius, the triangular fibrocartilage, and the scaphoid, semilunar, and cuneiform bones of the carpus.

The Third,—between all the carpal bones except the pisiform and between the bases of the inner 4 metacarpal bones; but it extends only halfway into the 2 intervals between the 3 proximal bones of the carpus.

The Fourth,—between the trapezium and the metacarpal bone of the thumb.

The Fifth,—between the cuneiform and pisiform bones.

The Metacarpo-metacarpal Articulations. The 4 inner metacarpal bones are connected together at their bases by Dorsal, Palmar, and Interosseous Ligaments, and at their digital extremities by the Transverse Ligament, a narrow fibrous band which crosses them anteriorly.

Remaining Articulations of the Hand. The metacarpo-phalangeal are condyloid joints formed by the rounded heads of the metacarpal bones and the shallow cavities in the extremities of the first phalanges. The phalangeal articulations are ginglymus joints. Both sets have for each joint an Anterior and 2 Lateral Ligaments, the former being lined each with a synovial membrane. There are no posterior ligaments to these articulations, the extensor tendons of the hand supplying their places.

### ARTICULATIONS OF THE LOWER EXTREMITY.

The Hip-joint is a true enarthrodial or ball-and-socket articulation, formed by the head of the femur with the acetabulum of the os innominatum. Its Synovial Membrane is extensive, investing most of the head and neck of the femur, the capsular, cotyloid and teres ligaments, and the cavity of the acetabulum. Its Arteries are derived from the obturator, sciatic, internal circumflex, and gluteal. Its Nerves are branches from the sacral plexus, great sciatic, obturator, and accessory obturator. It has 5 ligaments, as follows: the—

Capsular,—from the margin of the acetabulum and the transverse ligament into the base of the neck of the femur above, the anterior intertrochanteric line in front, and to the middle of the neck of the bone, behind. Superadded to and strengthening it are 3 auxiliary bands, the fibres of which form part of the capsule,—the ilio-jemoral (described below), the ischio-jemoral and the pectineo-jemoral bands.

Ilio-jemoral or Y-ligament,—from the anterior inferior spine of the ilium, into the anterior inter-trochantetic line by two fasciculi. It is a dissected portion of the capsular ligament which is very strong anteriorly.

Ligamentum Teres,—from a depression on the head of the femur into the margins of the cotyloid notch of the acetabulum and into the transverse ligament, by two fasciculi.

Cotyloid,—a fibro-cartilaginous band surrounding the margin of the acetabulum in order to deepen its cavity.

Transverse,—that part of the cotyloid ligament which crosses over the cotyloid notch converting it into a foramen.

The Knee-joint is a complicated articulation, formed by the condyles of the femur with the head of the tibia and the patella in front. It consists of 3 articulations in one; those between the condyles of the femur and the tuberosities of the tibia are condyloid joints, while that between the patella and the femur is partly arthrodial. Its Synovial Membrane is the largest in the body, being reflected for 2 or 3 inches over the anterior surface of the femur, where it is supported by the subcrureus muscle; also over its condyles, the patella, semilunar cartilages, crucial ligaments, and the head of the tibia; and it is prolonged through an opening in the capsular ligament beneath the tendon of the popliteus. Its Arteries are derived from the anastomotica magna, the articular branches of the popliteal, the recurrent branches of the anterior tibial and the external circumflex of the profunda. Its Nerves are derived from the obturator, anterior crural, external and internal popliteal. It has 14 ligaments, of which 6 are external and 8 internal, as follows:—

Anterior, or Ligamentum Patellæ,—is the central portion of the common

FIG. 40.

tendon of the extensor muscles of the thigh, continued from the patella to the tubercle of the tibia (o Fig. 41).

Posterior or Ligamentum Winslowii (1),—from the upper margin of the intercondyloid notch of the femur to the posterior margin of the head of the tibia, being partly derived from the tendon of the semimembranosus muscle (2).

Internal Lateral (5),—from the internal condyle of the femur to the inner tuberosity of the tibia and the internal semilunar cartilage.

External Lateral 2,—from the external condyle of the femur to the head of the fibula. These ligaments are a Long (6) anteriorly and a Short (7) posteriorly, separated by the tendon of the biceps.

The Internal Ligaments are as follows:-

Anterior Crucial (2),—from the depression in front of the spine of the tibia to the inner side of the outer condyle of the femur.

Posterior Crucial (3),—from the depression behind the spine of the tibia

and the popliteal notch, to the outer side of the inner condyle of the femur. [To remember the positions and insertions of these crucial ligaments, let the student cross his index fingers over each knee in succession; when over the right knee placing the right finger in front, when over the left knee the left finger in front. The positions of the fingers will in each case correspond with those of the respective crucial ligaments.]

Semilunar Fibro-cartilages 2,—external (7) and internal (6), are situated between the articular surfaces, and attached to the depressions in front and behind the spine of the tibia. The external one forms nearly an entire circle and gives off posteriorly a strong fasciculus, the ligament of

Wrisberg, which is inserted into the inner condyle of the femur.

Transverse (4),—is a connecting slip between the semilunar fibro-cartilages anteriorly.

 $\mathsf{Digitized}\,\mathsf{by}\,Google$ 

Coronary (7),—are short bands connecting the outer margins of the fibrocartilages with the margin of the head of the tibia.

Ligamentum Mucosum,—is a triangular fold of the synovial membrane which at the lower border of the patella is given off to the intercondyloid notch of the femur.

Ligamenta Alaria,—are two fringe-like folds on the sides of the ligamentum mucosum, and are attached to the semilunar cartilages.

Bursæ,—in the vicinity of this joint are 12 in number; 3 in front, 4 on the outer side, and 5 on the inner side. Some of these are expansions from others, some often communicate with the joint, and some are only occasionally present. That between the patella and the skin is the one implicated in the affection called "house-maid's knee."

The Tibio-fibular Articulations are 3 in number, as follows, viz.—

SUPERIOR TIBIO-FIBULAR ARTICULATION, is an arthrodial joint, formed by the contiguous surfaces of the bones. It has a *Synovial Membrane* which is sometimes continuous with that of the knee-joint, and 3 ligaments, the—

Capsular,—a membranous bag surrounding the joint and much thicker in front than behind.

Anterior and Posterior Superior Tibio-fibular (10),—which connect the head of the fibula with the outer tuberosity of the tibia.

MIDDLE TIBIO-FIBULAR ARTICULATION. The shafts of these bones do not touch each other, but are connected by an *Interosseous Membrane* extending between their contiguous borders, and perforated, above for the anterior tibial vessels, below for the anterior peroneal vessels.

INFERIOR TIBIO-FIBULAR ARTICULATION, is an amphiarthrodial joint, at the subdivision syndesmosis, and is formed by the contiguous rough surfaces on the lower ends of these bones. Its Synovial Membrane is derived from that of the ankle-joint, and it has 4 ligaments, the—

Inferior Interosseous,—continuous with the interosseous membrane.

Anterior and Posterior Inferior Tibio-fibular,—from the margins of the external malleolus to the front and back of the tibia.

Transverse,—posteriorly between the 2 malleoli.

The Ankle-joint is a ginglymus or hinge-joint articulation, formed by the lower ends of the tibia and fibula and their malleoli, with the astragalus. Its Synovial Membrane is prolonged upward between the tibia and fibula for a short distance. Its Arteries are derived from the malleolar branches of the anterior tibial and peroneal arteries; and its Nerves from the anterior and posterior tibial nerves. It has 4 ligaments; the—

Anterior,—connecting the anterior margins of the tibia and astragalus.

Posterior,—a very thin band of transverse fibres, connecting the posterior margins of the tibia and astragalus.

Internal Lateral or Deltoid Ligament,—from the internal malleolus to the 3 adjacent tarsal bones.

External Lateral,—by anterior, posterior and middle fasciculi, from the external malleolus to the astragalus and os calcis.

The Tarsal Articulations are connected by the following-named ligaments, viz. the—

Calcaneo-astragaloid 3, external, internal and posterior,—connecting the os calcis with the astragalus.

Calcaneo-cuboid 4, superior, internal, long and short,—connecting the os calcis with the cuboid.

Calcaneo-navicular 2, superior and inferior,—connecting the os calcis with the scaphoid or navicular bone.

Astragalo-navicular, superior,—connecting the astragalus with the scaphoid or navicular bone.

Dorsal and Plantar Ligaments,—connecting the scaphoid with the three cuneiform and with the cuboid, the three cuneiform with each other, and the external cuneiform with the cuboid.

Interosseous Ligaments,—connecting the os calcis with the astragalus, the scaphoid with the cuboid, the cuneiform bones with each other, and the external cuneiform with the cuboid.

Nerves. All the joints of the tarsus are supplied by the anterior tibial nerve.

The Tarso-metatarsal Articulations are 5 arthrodial joints formed by the bases of the metatarsal bones with the adjacent bones of the tarsus, the 2d metatarsal bone articulating with all 3 cuneiform in the recess formed by the shortness of the second cuneiform. They are united by Dorsal, Plantar, and 3 Interosseous Ligaments. The 2d metatarsal bone has 3 dorsal ligaments, 1 from each cuneiform bone. The interosseous ligaments pass from the 2d and 3d metatarsal bones to the internal and external cuneiform.

Synovial Membranes of the Tarsus and Metatarsus are 6 in number, and are situated as follows, viz.—

First,—between the os calcis and the astragalus, behind the interosseous ligament.

Second,—between the same bones in front of the interosseous ligament, also between the astragalus and the scaphoid.

Third,—between the os calcis and the cuboid.

Fourth,—between the scaphoid and the 3 cuneiform bones, running back-

ward between the scaphoid and the cuboid, forward between the cuneiform bones, between the external cuneiform and the cuboid, between the middle and external cuneiform and the bases of the 2d and 3d metatarsal, passing also between the bases of these bones and the 4th metatarsal.

Fifth,—between the internal cuneiform and the base of the 1st metatarsal bone.

Sixth,—between the cuboid and the 4th and 5th metatarsal bones, also running forward between their bases.

The Metatarso-metatarsal Articulations. The metatarsal bones are connected together, except the first, at their bases by Dorsal, Plantar, and Interosseous Ligaments. The base of the first metatarsal is not connected with the base of the second by any ligaments, resembling the thumb in this respect.

Remaining Articulations of the Foot. The metatarso-phalangeal and the phalangeal articulations are similar to those in the hand, each having a *Plantar* and 2 *Lateral Ligaments*. The extensor tendons of the foot supply the places of the posterior ligaments.

# THE MUSCLES AND FASCIÆ.

The Muscles are the active organs of locomotion, formed of bundles of reddish fibres endowed with the property of shortening themselves upon irritation, which is called *muscular contractility*, and chemically consisting of 75 per cent. of water, 20 of proteids, 2 of fat, 1 of nitrogenous extractives and carbohydrates, and 2 per cent. of salts, mainly potassium phosphate and carbonate.

The Muscles are divided into 2 great classes,—Voluntary, Striped, or Muscles of animal life, comprise those which are under the control of the will Involuntary, Unstriped, or Muscles of organic life, are those which are not under the control of the will.

Voluntary Muscular Fibre consists of *fasciculi* enclosed in a delicate web, the *perimysium*, connected together by a delicate connective tissue, the *endomysium*, aggregated into muscular fibres, from  $\frac{1}{500}$  inch to  $\frac{1}{200}$  inch in diameter, which are enclosed in tubular sheaths, the *sarcolemma*, and are marked by fine *striæ* passing around them transversely or somewhat obliquely. The fasciculi are formed of longitudinal fibrilæ or *sarcostyles*, made up of successive portions called *sarcomeres*, each of which consists of a

central dark part. the sarcous element, and a clear layer which is most visible when the fibre is extended (Schäfer).

Involuntary Muscular Fibre is made up of spindle-shaped cells, the contractile fibre-cells, averaging  $\frac{1}{4}\frac{1}{50}$  inch long and  $\frac{1}{4000}$  inch broad, collected into bundles and held together by a cement-like substance. These are aggregated into larger bundles or flattened bands, bound together by ordinary connective tissue. Involuntary muscular fibres are found in the walls of the alimentary canal, in the posterior wall of the trachea, in the bronchi, the ducts of certain glands, in the ureters, bladder, urethra, genitalia of both sexes, walls of all arteries and most veins and lymphatics, in the iris and ciliary muscle, and in the skin.

Tendons and Aponeuroses. Tendons are white, glistening cords or bands formed of white fibrous tissue almost entirely, have few vessels and no nerves in the smaller ones. They serve to connect the muscles with the structures on which they act. Aponeuroses are fibrous membranes, of similar structure and appearance, and serve the same purpose.

Fasciæ are laminæ of variable thickness which invest (Jascia, a bandage) the softer structures. The superficial jascia is composed of fibro-areolar tissue, and is found beneath the skin over almost the whole body. The deep Jascia is of aponeurotic structure, dense, inelastic, and fibrous, ensheathing the muscles and affording some of them attachment, also enclosing the vessels and nerves, and binding down the whole into a shapely mass.

Muscles are attached to the periosteum and perichondrium of bone and cartilage, to the subcutaneous areolar tissue, and to ligaments. In the latter case only are their tendons in direct contact with the tissue on which they are to act.

**Double-bellied Muscles** are 5 in number, the—occipito-frontalis, biventer cervicis, digastric, omo-hyoid, and the diaphragm.

### MUSCLES OF THE HEAD.

CRANIAL REGION.

Occipito-frontalis (a),—arises from the external two-thirds of the superior curved line of the occipital bone and the mastoid process of the temporal; also from the pyramidalis nasi, corrugator supercilii, and orbicularis palpebrarum fibres; and is inserted into an aponeurosis or "galea capitis," which covers the vertex of the skull. Action, chiefly as a muscle of facial expression. Nerves, the frontal portion by the facial nerve, the occipital portion by the posterior auricular branch of the facial.

### AURICULAR REGION.

Attrahens Auriculam,—*from* the lateral cranial aponeurosis: *into* the helix of the ear anteriorly. *Action*, to draw the pinna forward. *Nerve*, temporal branch of the facial.

Attollens Auriculam,—from the occipito-frontalis aponeurosis: into the pinna of the ear superiorly. Action, to raise the pinna. Nerve, temporal branch of the facial.

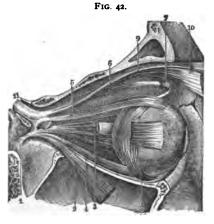

Retrahens Auriculam,—*from* the mastoid process of the temporal bone *into* the concha. *Action*, to retract the pinna. *Nerve*, posterior auricular branch of the facial.

### PALPEBRAL REGION.

Orbicularis Palpebrarum,—*from* the internal angular process of the frontal bone, the nasal process of the superior maxillary, and the borders of the tendo oculi; *into* the skin of the eyelids, forehead, temple, and cheek, blending with the occipito-frontalis and the corrugator supercilii. *Action*, to close the eyelids. *Nerve*, facial; perhaps by the 3d nerve.

Corrugator Supercilii,—from the inner end of the superciliary ridge of the frontal bone: into the orbicularis palpebrarum. Action, to draw eyebrow downward and inward. Nerve, facial; perhaps by the 3d nerve.

Tensor Tarsi (Horner's muscle),—from the crest of the lachrymal bone:

into the tarsal cartilages by two slips. Action, to compress the puncta lachrymalia against the globe of the eye, and to compress the lachrymal sac. Nerve, facial; perhaps by the 3d nerve.

ORBITAL REGION.

Levator Palpebræ Superioris (9),—from the lesses wing of the sphenoid: into the upper tarsal cartilage Action, to lift the upper lid. Nerve, 3d cranial, or motor oculi.

Rectus Superior (5),—from the upper margin of the

optic foramen and the sheath of the optic nerve: into the sclerotic coat Action, to rotate the eyeball upward. Nerve, 3d cranial.

Rectus Inferior (4),—*from* the ligament of Zinn: *into* the sclerotic coat.

Action, to rotate the eyeball downward. Nerve, 3d cranial.

Rectus Internus (3),—from the ligament of Zinn: into the sclerotic coat.

Action, to rotate the eyeball inward. Nerve, 3d cranial.

Rectus Externus (2),—by 2 heads, the upper from the outer margin of the optic foramen, the lower from the ligament of Zinn and a bony process at lower margin of the sphenoidal fissure: into the sclerotic coat Action, to rotate the eyeball outward. Nerve, 6th cranial, or abducens.

Between the 2 heads of the external rectus pass the 3d, nasal branch of the 5th, and the 6th cranial nerves, and the ophthalmic vein.

Obliquus Oculi Superior (6),—from about a line above the inner margin of the optic foramen, its tendon passing through a pulley (7) near the internal angular process of the frontal bone and thence beneath the rectus superior: into the sclerotic coat at right angles to the insertion of the rectus superior. Action, to rotate the eyeball on its antero-posterior axis. Nerve, 4th cranial, or patheticus.

Obliquus Oculi Inferior (8),—from the orbital plate of the superior maxillary: into the sclerotic coat below the insertion of the external rectus and

at right angles thereto. Action, to rotate the eye on its antero-posterior axis. Nerve, 3d cranial.

### NASAL REGION.

Pyramidalis Nasi (c),—from the occipito-frontalis: into the compressor naris. Action, to depress the eyebrow. Nerve, facial.

Levator Labii Superioris Alæque Nasi (e),—from the nasal process of the superior maxillary bone: into the cartilage of the ala of the nose and into the upper lip. Action, to elevate the upper lip, and dilate the nostril. Nerve, facial.

Dilator Naris Anterior,—/rom the cartilage of the ala: into the border

cartilage of the ala: *into* the border of its integument. *Action*, to dilate the nostril. *Nerve*, facial.

Dilator Naris Posterior,-from the nasal notch of the superior maxillary

Digitized by GOOGLE.

- and the sesamoid cartilages: into the integument at the margin of the nostril. Action, to dilate the nostril. Nerve, facial.
- Compressor Nasi (d),—from the superior maxillary above the incisive fossa: into the fibro-cartilage of the nose, being continuous with its fellow and the pyramidalis nasi aponeurosis. Action, to dilate the nostril. Nerve, facial.
- Compressor Narium Minor,—from the alar cartilage: into the skin at the end of the nose. Action, to dilate the nostril. Nerve, facial.
- Depressor Alæ Nasi,—from the incisive fossa of the superior maxillary: into the septum and ala of the nose. Action, to contract the nostril. Nerve, facial.

### SUPERIOR MAXILLARY REGION.

- Levator Labii Superioris (f),—from the lower margin of the orbit: into the upper lip. Action, to elevate the lip. Nerve, facial.
- Levator Anguli Oris (o)—from the canine fossa of the superior maxillary: into the angle of the mouth. Action, as named. Nerve, facial.
- **Zygomaticus Major** (h),—from the malar bone: into the angle of the mouth. Action, to raise the lip outward. Nerve, facial.
- Zygomaticus Minor (g),—from the malar bone anteriorly: into the angle of the mouth, blending with the levator labii superioris. Action, to raise the lip outward. Nerve, facial.

### INFERIOR MAXILLARY REGION.

- Levator Labii Inferioris (m)—(Levator Menti), from the incisive fossa of the inferior maxillary bone: into the integument of the chin. Action, as named. Nerve, facial.
- Depressor Labii Inferioris (1) (Quadratus Menti),—from the external oblique line of the inferior maxillary bone: into the lower lip. Action, as named. Nerve, facial.
- Depressor Anguli Oris (n) (Triangularis Menti),—from the external oblique line of the inferior maxillary: into the angle of the mouth. Action, as named. Nerve, facial.

### INTER-MAXILLARY REGION.

Orbicularis Oris (k),—by accessory fibres (accessorii orbicularis superioris and inferioris, and naso-labialis) from the nasal septum and the superior and inferior maxillary borders: into the buccinator and other adjacent muscles, forming the sphincter of the mouth. Action, to close the mouth. Nerve, facial.

- Buccinator (j),—from the posterior alveolar processes of both the maxillary bones and the pterygo-maxillary ligament: into the orbicularis oris. Action, to compress the cheeks. Nerves, facial, and the buccal branch of the inferior maxillary.
- Risorius,—from the fascia over the masseter muscle: into the angle of the mouth. Action, the laughing muscle. Nerve, facial.

## TEMPORO-MANDIBULAR REGION.

- Masseter (i),—from the anterior two-thirds and the inner surface of the zygoma and the malar process of the superior maxillary: into the angle, ramus, and coronoid process of the lower jaw. Action, to raise the back part of the lower jaw; a muscle of mastication. Nerve, inferior maxillary.
- Temporal,—/rom the temporal fossa and temporal fascia: into the coronoid process of the inferior maxillary. Action, to bring the incisor teeth together; the biting muscle. Nerve, inferior maxillary.

### PTERYGO-MANDIBULAR REGION.

- External Pterygoid,—by 2 heads, the upper, from the pterygoid ridge on the greater wing of the sphenoid, the lower from the external pterygoid plate, and the tuberosities of the palate and superior maxillary bones: into a depression in front of the condyle of the inferior maxillary, and the interarticular fibro-cartilage. Action, to draw the jaw forward; a triturating muscle of mastication. Nerve, inferior maxillary.
- Between the two heads of the external pterygoid muscle passes the internal maxillary artery.
- Internal Pterygoid,—*from* the pterygoid fossa of the sphenoid bone, and the tuberosity of the palate: *into* the angle and inner surface of the ramus of the jaw, as high as the dental foramen. *Action*, raises and draws forward the lower jaw; a triturating muscle of mastication. *Nerve*, inferior maxillary.

### MUSCLES OF THE EAR.

The muscles of the ear include those of the pinna and those of the tympanum. The former are divided into two sets: Extrinsic,—the attrahens, attollens and retrahens auriculam (see page 76); and the Intrinsic, as follows:—

### INTRINSIC MUSCLES OF THE PINNA

Helicis Major,—from the cauda helicis: into the anterior border of the helix. Nerve, facial.

Helicis Minor,—an oblique fasciculus which covers the crus helicis. Nerve. facial.

- Tragicus,—a short, vertical band of muscular fibres, on the outer surface of the tragus. Nerve, facial.
- Antitragicus,—/rom the antitragus: into the cauda helicis and antihelix.

  Nerve, facial.
- Transversus Auriculæ,—on the cranial surface of the pinna, *from* the convexity of the concha: *into* the prominence corresponding to the groove of the helix. *Nerve*, facial.
- Obliquus Auriculæ,—from the upper and back part of the concha: into the convexity immediately above it. Nerve, facial

#### MUSCLES OF THE TYMPANUM.

- Tensor Tympani,—/rom the under surface of the petrous portion of the temporal bone, the cartilaginous Eustachian tube, and its own osseous canal: into the handle of the malleus. Action, to draw the membrana tympani inward and tense. Nerve, branch from otic ganglion.
- Stapedius,—from the interior of the pyramid, through the orifice at its apex: into the neck of the stapes. Action, to rotate the base of the stapes and compress the contents of the vestibule. Nerve, tympanic branch of the facial.

# MUSCLES OF THE NECK.

### SUPERIOR CERVICAL REGION.

- Platysma Myoides,—from the fascia covering the pectoral and deltoid muscles: into the lower jaw, the angle of the mouth, the skin, and the cellular tissue of the face. Action, to wrinkle the skin, and depress the mouth. Nerve, facial.
- Sterno-cleido-mastoid (11),—by two heads from the sternum (12) and the clavicle (13) at its inner third: into the mastoid process of the temporal bone, and the outer half of the superior curved line of the occipital. Action, to depress and rotate the head. Nerves, spinal accessory, and deep branches of the cervical plexus.

### INFRA-HYOID REGION.

- Sterno-hyoid (14),—/rom the posterior surface of the sternum and the sternal end of the clavicle: into the body of the hyoid bone. Action, to depress the hyoid bone. Nerve, a branch from the communicating loop between the descendens and communicans hypoglossi.
- Sterno-thyroid (15),—from the posterior surface of the sternum and the cartilage of the 1st rib: into the oblique line on the ala of the thyroid carti-

lage. Action, to depress the thyroid cartilage. Nerve, a branch from the

communicating loop between the descendens and communicans hypoglossi.

Thyro-hyoid (16),—

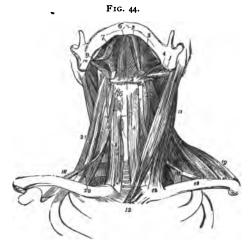

from the oblique line
on the thyroid cartilage: into the body
and greater cornu
of the hyoid bone.

Action, to depress the
larynx and the hyoid
bone. Nerve, hypoglossal.

Omo-hyoid (17, 18),—

from the upper border

of the scapula and
the transverse ligament: into the body

of the hyoid bone. It has a tendon in its centre which is bound down to the clavicle and the 1st rib by a loop of the deep cervical fascia. Action, to depress the hyoid bone, and draw it backward. Nerve, branch from the communicating loop between the descendens and communicans hypoglossi.

### SUPRA-HYOID REGION.

Digastric,—by 2 bellies, the posterior one (1) from the digastric groove of the mastoid process of the temporal bone; the anterior (2) from a fossa on the inner surface of the inferior maxillary, near its symphysis: into a central tendon (3) which perforates the stylo-hyoid muscle, and is bound down to the body of the hyoid bone by an aponeurotic loop. Action, to raise the hyoid bone and tongue. Nerves, facial, and mylo-hyoid branch of the inferior dental.

Stylo-hyoid (4),—from the styloid process of the temporal bone near its base: into the body of the hyoid bone. Action, to elevate and retract the hyoid bone. Nerve, facial. This muscle is perforated by the digastric.

Mylo-hyoid (5),—from the mylo-hyoid ridge of the lower jaw: into the body of the hyoid bone and a median fibrous raphé line running from the hyoid bone to the lower jaw. Action, elevates the hyoid bone and draws it for-

- ward, also forms the floor of the mouth. Nerve, mylo-hyoid branch of inferior dental.
- Genio-hyoid (6),—from the inferior genial tubercle of the inferior maxillary: into the body of the hyoid bone. Action, same as that of the mylo-hyoid. Nerve, hypoglossal.

### LINGUAL REGION.

- Genio-hyo-glossus,—from the superior genial tubercle of the inferior maxillary: into the body of the hyoid bone, the side of the pharynx, and the whole length of the under surface of the tongue, forming a fan-like muscle. Action, to retract and protrude the tongue. Nerve, hypoglossal.
- Hyo-glossus (8),—from the side of the body of the hyoid bone, and the whole length of its greater cornu: into the side of the tongue. Action, to to draw down the side of the tongue. Nerve, hypoglossal.
- Chondro-glossus,—sometimes described as a part of the hyo-glossus, from the lesser cornu and the body of the hyoid bone: into the intrinsic muscular fibres of the tongue, between the hyo-glossus and the genio-hyo-glossus. Action, as the hyo-glossus. Nerve, hypoglossal.
- Stylo-glossus (9),—from the styloid process and the stylo-mandibular ligament: into the side of the tongue and the hyo-glossus muscle. Action, to elevate and retract the tongue. Nerve, hypoglossal.
- Palato-glossus,—is one of the muscles of the tongue, serving to draw its base upward, but is described with the muscles of the palatal region.
- Lingualis, (the tongue-muscle), in 4 strata,—superior lingualis, composed of fibres passing forward and outward; stratum derived principally from the extrinsic muscles, the stylo-glossus, hyo-glossus, etc.; transverse lingualis and vertical lingualis, the latter found only at the borders of the fore part of the tongue; inferior lingualis and fibres from the stylo-glossus. Action, to give the tongue its various forms. Nerve, the hypoglossal is the motor nerve of the tongue.

# PHARYNGEAL REGION.

- Inferior Constrictor,—from the sides of the cricoid and thyroid cartilages: into the fibrous raphé of the pharynx. Action, to contract the pharyngeal calibre. Nerves, branches from the pharyngeal plexus, external laryngeal, recurrent laryngeal.
- Middle Constrictor,—from the cornua of the hyoid bone and the stylo-hyoid ligament: into the fibrous pharyngeal raphé. Action, to constrict the pharynx. Nerves, branches from the pharyngeal plexus.
- Superior Constrictor,—from the lower third of the margin of the internal

pterygoid plate and its hamular process, the contiguous part of the palate bone, the tendon of the tensor palati, the pterygo-maxillary ligament, part of the alveolar process of the lower jaw and the side of the tongue: *into* the fibrous pharyngeal raphé and the pharyngeal spine of the occipital bone. *Action*, to constrict the pharynx. *Nerves*, branches from the pharyngeal plexus.

Stylo-pharyngeus (10),—from the inner side of the base of the styloid process: into the constrictor and palato-pharyngeus muscles, and the thyroid cartilage. Action, to elevate the pharynx. Nerve, glosso-pharyngeal nerve which crosses this muscle in passing to the tongue.

### PALATAL REGION.

- Levator Palati,—/rom the under surface of the apex of the petrous portion of the temporal bone and from the Eustachian tube: into the posterior surface of the soft palate. Action, to elevate the soft palate. Nerve, facial, through the petrosal branch of the Vidian.
- Tensor Palati,—from the scaphoid fossa and the spine of the sphenoid bone and the Eustachian tube, reflected around the hamular process: into the anterior surface of the soft palate, and the horizontal portion of the palate bone. Action, to make tense the soft palate. Nerve, a branch from the otic ganglion.
- Azygos Uvulæ,—from the posterior nasal spine of the palate bone, and from the soft palate: into the uvula. Action, possibly to raise the uvula. This muscle is wrongly named, as it is a double muscle. Nerve, probably by the internal branch of the spinal accessory.
- Palato-glossus (constrictor isthmi faucium),—from the anterior surface of the soft palate on the side of the uvula: into the side and dorsum of the tongue. Action, to constrict the fauces. It forms the anterior pillar of the fauces. Nerve, probably the internal branch of the spinal accessory.
- Palato-pharyngeus (posterior pillar of the fauces),—from the soft palate: into the side of the pharynx and the posterior border of the thyroid cartilage, having joined the stylo-pharyngeus. Action, to close the posterior nares. Nerve, probably the internal branch of the spinal accessory.
- Salpingo-pharyngeus,—from the Eustachian tube near its orifice: into the posterior fasciculus of the palato-pharyngeus. Action, to raise the upper and lateral part of the pharynx. Nerve, probably the internal branch of the spinal accessory.

### ANTERIOR VERTEBRAL REGION.

Rectus Capitis Anti'cus Major,—from the anterior tubercles of the transverse processes of the 3d, 4th, 5th, and 6th cervical vertebræ by 4 slips:

- ward, also forms the floor of the mouth. Nerve, mylo-hyoid branch of inferior dental.
- Genio-hyoid (6),—/rom the inferior genial tubercle of the inferior maxillary: into the body of the hyoid bone. Action, same as that of the mylo-hyoid. Nerve, hypoglossal.

### LINGUAL REGION.

- Genio-hyo-glossus,—from the superior genial tubercle of the inferior maxillary: into the body of the hyoid bone, the side of the pharynx, and the whole length of the under surface of the tongue, forming a fan-like muscle. Action, to retract and protrude the tongue. Nerve, hypoglossal.
- Hyo-glossus (8),—*from* the side of the body of the hyoid bone, and the whole length of its greater cornu: *into* the side of the tongue. *Action*, to to draw down the side of the tongue. *Nerve*, hypoglossal.
- Chondro-glossus,—sometimes described as a part of the hyo-glossus, from the lesser cornu and the body of the hyoid bone: into the intrinsic muscular fibres of the tongue, between the hyo-glossus and the genio-hyo-glossus. Action, as the hyo-glossus. Nerve, hypoglossal.
- Stylo-glossus (9),—from the styloid process and the stylo-mandibular ligament: into the side of the tongue and the hyo-glossus muscle. Action, to elevate and retract the tongue. Nerve, hypoglossal.
- Palato-glossus,—is one of the muscles of the tongue, serving to draw its base upward, but is described with the muscles of the palatal region.
- Lingualis, (the tongue-muscle), in 4 strata,—superior lingualis, composed of fibres passing forward and outward; stratum derived principally from the extrinsic muscles, the stylo-glossus, hyo-glossus, etc.; transverse lingualis and vertical lingualis, the latter found only at the borders of the fore part of the tongue; in/erior lingualis and fibres from the stylo-glossus. Action, to give the tongue its various forms. Nerve, the hypoglossal is the motor nerve of the tongue.

#### PHARYNGEAL REGION.

- Inferior Constrictor,—from the sides of the cricoid and thyroid cartilages: into the fibrous raphé of the pharynx. Action, to contract the pharyngeal calibre. Nerves, branches from the pharyngeal plexus, external laryngeal, recurrent laryngeal.
- Middle Constrictor,—from the cornua of the hyoid bone and the stylo-hyoid ligament: into the fibrous pharyngeal raphé. Action, to constrict the pharynx. Nerves, branches from the pharyngeal plexus.
- Superior Constrictor,—/rom the lower third of the margin of the internal

pterygoid plate and its hamular process, the contiguous part of the palate bone, the tendon of the tensor palati, the pterygo-maxillary ligament, part of the alveolar process of the lower jaw and the side of the tongue: *into* the fibrous pharyngeal raphé and the pharyngeal spine of the occipital bone. *Action*, to constrict the pharynx. *Nerves*, branches from the pharyngeal plexus.

Stylo-pharyngeus (10),—from the inner side of the base of the styloid process: into the constrictor and palato-pharyngeus muscles, and the thyroid cartilage. Action, to elevate the pharynx. Nerve, glosso-pharyngeal nerve which crosses this muscle in passing to the tongue.

### PALATAL REGION.

- Levator Palati,—from the under surface of the apex of the petrous portion of the temporal bone and from the Eustachian tube: into the posterior surface of the soft palate. Action, to elevate the soft palate. Nerve, facial, through the petrosal branch of the Vidian.
- Tensor Palati,—from the scaphoid fossa and the spine of the sphenoid bone and the Eustachian tube, reflected around the hamular process: into the anterior surface of the soft palate, and the horizontal portion of the palate bone. Action, to make tense the soft palate. Nerve, a branch from the otic ganglion.
- Azygos Uvulæ,—*from* the posterior nasal spine of the palate bone, and from the soft palate: *into* the uvula. Action, possibly to raise the uvula. This muscle is wrongly named, as it is a double muscle. Nerve, probably by the internal branch of the spinal accessory.
- Palato-glossus (constrictor isthmi faucium),—from the anterior surface of the soft palate on the side of the uvula: into the side and dorsum of the tongue. Action, to constrict the fauces. It forms the anterior pillar of the fauces. Nerve, probably the internal branch of the spinal accessory.
- Palato-pharyngeus (posterior pillar of the fauces),—from the soft palate: into the side of the pharynx and the posterior border of the thyroid cartilage, having joined the stylo-pharyngeus. Action, to close the posterior nares. Nerve, probably the internal branch of the spinal accessory.
- Salpingo-pharyngeus,—/rom the Eustachian tube near its orifice: into the posterior fasciculus of the palato-pharyngeus. Action, to raise the upper and lateral part of the pharynx. Nerve, probably the internal branch of the spinal accessory.

### ANTERIOR VERTEBRAL REGION.

Rectus Capitis Anti'cus Major,—'rom the anterior tubercles of the transverse processes of the 3d, 4th, 5th, and 6th cervical vertebræ by 4 slips:

- into the basilar process of the occipital bone. Action, to flex and rotate the head. Nerves, first cervical and the loop between it and the second. This muscle appears like a continuation of the scalenus anticus.
- Rectus Capitis Anti'cus Minor,—'from the anterior surface of the lateral mass of the atlas, and the root of its transverse process,—into the basilar process of the occipital bone. Action, to flex and rotate the head. Nerves, as the rectus capitis anticus major.
- Rectus Capitis Lateralis,—from the upper surface of the transverse process of the atlas: into the jugular process of the occipital bone. Action, to draw the head laterally. Nerves as the preceding muscles.
- Longus Colli, 3 portions,—the superior oblique, from the anterior tubercles of the transverse processes of the 3d, 4th, and 5th cervical vertebræ, into a tubercle on the anterior arch of the atlas:—injerior oblique, from the bodies of the first 2 or 3 dorsal vertebræ, into the transverse processes of the 5th and 6th cervical:—vertical portion, from the bodies of the lower 3 cervical and upper 3 dorsal vertebræ, to the bodies of the 2d, 3d, and 4th cervical. Action, to flex and slightly rotate the cervical portion of the spine. Nerves, branches from the anterior divisions of the lower cervical nerves.

### LATERAL VERTEBRAL REGION.

- Scalenus Anti'cus (20),—from the transverse processes of the cervical vertebre, from the 3d to the 6th inclusive: into the scalene tubercle on the upper surface of the 1st rib. Action, to flex the neck laterally, or to raise the 1st rib. Nerves, branches from the lower cervical. (See Fig. 44.)
- Scalenus Medius (22),—/rom the transverse processes of the lower 6 cervical vertebræ: into the upper surface of the 1st rib, behind the subclavian groove. Action, same as the scalenus anticus. Nerves, branches from the lower cervical.
- Scalenus Posti'cus (21),—/rom the posterior tubercles on the transverse processes of the lower 2 or 3 cervical vertebræ: into the outer surface of the 2d rib, behind the serratus magnus. Action, to flex the neck laterally, or to elevate the 2d rib. Nerves, branches from lower cervical.

### MUSCLES OF THE LARYNX AND EPIGLOTTIS.

MUSCLES OF THE VOCAL CORDS AND RIMA GLOTTIDIS.

Crico-thyroid,—from the front and side of the cricoid cartilage (b): into the lower and inner borders of the thyroid cartilage (c). Action, to elongate and make tense the vocal cords. Nerve, external laryngeal.

Crico-arytenoideus Posticus,-/rom the cricoid cartilage posteriorly: into

the outer angle of the base of the arytenoid cartilage. Action, to rotate the arytenoid cartilages outward and open the glottis, while keeping the vocal cords tense. Nerve, recurrent laryngeal.

A small fasciculus, called Kerato-cricoideus, is sometimes found below the arytenoideus, extending from the cricoid cartilage to the inferior cornu of

the thyroid. It occurs once in 5 cases, usually on one side only, but occasionally on both, and acts to fix the lower horn of the thyroid cartilage backward and downward. [Sir Wm. Turner.]

Crico-arytenoideus Lateralis (d),—from the upper border of the cricoid cartilage laterally: into the outer angle of the base of the arytenoid cartilage. Action, to rotate the arytenoid cartilages inward and close the glottis. Nerve, recurrent laryngeal.

Arytenoideus,—/rom the posterior surface and outer border of one arytenoid cartilage: into the corresponding parts of the opposite cartilage. A single muscle which fills the posterior concave surface of these cartilages. Ac-

tion, by approximating the arytenoid, to close the back part of the glottis. Nerves, internal and recurrent laryngeal.

A fairly constant muscle, the *Arytenoideus rectus*, is found beneath the arytenoideus, extending from the posterior surface of the arytenoid cartilage to the posterior surface of the cartilage of Santorini [Luschka].

Thyro-arytenoideus (e),—/rom the receding angle of the thyroid cartilage and the crico-thyroid membrane: into the base and anterior surface of the arytenoid cartilage. Action, to shorten and relax the vocal cords by approximating the cartilages. Nerve, recurrent laryngeal.

#### MUSCLES OF THE EPIGLOTTIS.

Thyro-epiglottideus,—from the inner surface of the thyroid cartilage: into the margin of the epiglottis and the aryteno-epiglottidean fold. Action, a depressor of the epiglottis. Nerve, recurrent laryngeal.

Aryteno-epiglottideus Superior,—from the apex of the arytenoid cartilage: into the aryteno-epiglottidean folds. Action, to constrict the superior laryngeal aperture. Nerve, recurrent laryngeal.

Aryteno-epiglottideus Inferior,—from the arytenoid cartilage anteriorly:

into the auterior surface of the epiglottis. Action, to compress the sacculus laryngis. Nerve, recurrent laryngeal.

Another small muscle is frequently found, though rarely described in the books, the Triticeo-glossus. It arises from the cartilaginous nodule in the posterior thyro-hyoid ligament, and passes forward and upward to enter the tongue along with the hyo-glossus muscle. [Bochdalek, jun.]

### MUSCLES OF THE TRUNK.

The muscles of the trunk may be arranged in four groups, corresponding to the regions in which they are situated, viz.—those of the Back, the Thorax, the Abdomen, and the Perineum.

### MUSCLES OF THE BACK.

The muscles of the back may be arranged in 5 layers:—

FIRST LAYER—Trapezius. Latissimus Dorsi.

SECOND LAYER—Levator Anguli Scapulæ. Rhomboideus Major and Minor. THIRD LAYER—Serratus Posti'cus Superior. Serratus Posti'cus Inferior.

Splenius Capitis. Splenius Colli.

FOURTH LAYER, in 3 sets, viz.—

Sacral and Lumbar Regions.

Erector Spinæ.

Dorsal Region.

Ilio-costalis.

Musculus Accessorius ad Ilio-

costalem.

Longissimus Dorsi. Spinalis Dorsi.

FIFTH LAYER—six having the word spinal in them, viz.—

Semi-spinalis Dorsi. Semi-spinalis Colli.

Multifidus Spinæ.

Rotatores Spinæ.

Supra-spinales. Inter-spinales.

Cervical Region. Cervicalis Ascendens.

Transversalis Cervicis.

Trachelo-mastoid. Complexus.

Biventer Cervicis.

Spinalis Colli.

Extensor Coccygis. Inter-transversales.

Rectus Capitis Posti'cus Major. Rectus Capitis Posti'cus Minor.

Obliquus Capitis Inferior. Obliquus Capitis Superior.

#### FIRST LAVER.

Trapezius (1),-from the inner third of the superior curved line of the occipital bone, the ligamentum nuchæ (2), the spinous processes of the last cervical and all the dorsal vertebræ, and the supra-spinous ligament: into the outer third of the posterior border of the clavicle, the superior margin

of the acromion process, the whole length of the superior border of the spine of the scapula (3), and a tubercle at its inner extremity. Action, to draw the head backward. Nerves, spinal accessory, cervical plexus.

LIGAMENTUM NUCHÆ (2),—from the external occipital protuberance: to the spines of the cervical vertebræ, from the 2d to the 7th inclusive.

Latissimus Dorsi (4),—by an aponeurosis from the spines of the 6 lower

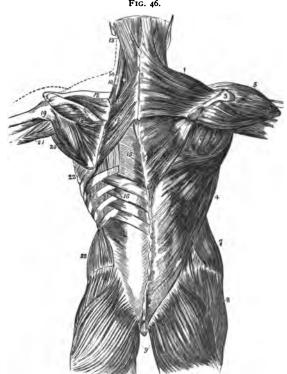

FIG. 46.

dorsal and the lumbar and sacral vertebræ, the supra-spinous ligament, the crest of the ilium and the 3 or 4 lower ribs: into the bicipital groove of the humerus. Action, the cursor ani muscle, drawing the arm downward and backward; or raising the lower ribs and drawing the trunk forward. Nerve, the middle or long subscapular.

 $\mathsf{Digitized} \ \mathsf{by} \ Google$ 

#### SECOND LAYER.

- Levator Anguli Scapulæ (10),—by 4 slips from the transverse processes of the atlas and 3 upper cervical vertebræ: *into* the posterior border of the scapula. *Action*, as named. *Nerves*, branches from the anterior divisions of the 3d, 4th and 5th cervical nerves.
- Rhomboideus Minor (11),—from the ligamentum nuchæ (2) and spines of the 7th cervical and 1st dorsal vertebræ: into the smooth surface at the root of the spine of the scapula. Action, to draw the scapula backward and upward. Nerve, branches from the anterior division of the 5th cervical.
- Rhomboideus Major (12),—/rom the spines of the 4 or 5 upper dorsal vertebræ and the supra-spinous ligament: into the scapula at the root of its spine and inferior angle, by a tendinous arch. Action, to draw the scapula upward and backward. Nerve, anterior division of the 5th cervical.
- Serratus Posti'cus Superior,—/rom the ligamentum nuchæ (2), and spines of the 7th cervical and 2 or 3 upper dorsal vertebræ: into the upper borders of the 2d, 3d, 4th, and 5th ribs, by 4 digitations. Action, to raise these ribs in inspiration. Nerves, external posterior branches of the upper dorsal nerves.
- Serratus Posti'cus Inferior (16),—/rom the spines of the last 2 dorsal and first 3 lumbar vertebræ: into the lower borders of the 4 lower ribs, by 4 digitations. Action, to depress these ribs in expiration. Nerves, external posterior branches of the lower dorsal nerves.
- Splenius (14),—from the lower half of the ligamentum nuchæ (2), the last cervical and 6 upper dorsal spines, and the supra-spinous ligament: the S. capitis (13) into the mastoid process of the temporal bone and a rough surface below the superior curved line of the occipital bone,—the S. colli (14) into the transverse processes of the 2 or 3 upper cervical vertebræ. Action, to draw the head backward and the neck erect. Nerves, external posterior branches of the cervical nerves.

# FOURTH LAYER. (See Fig. 47.)

- Erector Spinæ (1),—/rom the sacro-iliac groove, and by the lumbo-sacral tendon from the sacral, lumbar and 2 lower dorsal spines, the iliac crest, and the posterior eminences of the sacrum: divides into the ilio-costalis (2) and longissimus dorsi (3) muscles. Action, to erect the spine and bend the trunk backward. Nerves, external posterior branches of the lumbar nerves.
- Ilio-costalis (sacro-lumbalis) (2),—the external portion of the erector

spinæ: into the inferior borders of the angles of the 6 or 7 lower ribs. Action, as the erector spinæ. Nerves, branches of the dorsal.

Musculus Accessorius ad Ilio-costalem (2),—from the angles of 6 lower ribs: into the angles of 6 upper ribs. Action, as the erector spinæ. Nerves, branches of the dorsal.

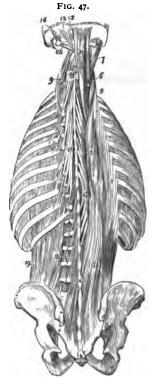

Cervicalis Ascendens (5),—from the angles of 4 or 5 upper ribs: into the transverse processes of the 4th, 5th, and 6th cervical vertebræ. Action, to keep the neck erect. Nerves, branches of the cervical.

Longissimus Dorsi (3),—is the middle and largest portion of the erector spinæ, and is inserted *into* the transverse and articular processes of the lumbar vertebræ, into the tips of the transverse processes of all the dorsal vertebræ, and into from 7 to 11 lower ribs between their tubercles and angles. Action, as the erector spinæ. Nerves, branches of the lumbar and dorsal nerves.

Transversalis Colli (6),—from the transverse processes of the 6 upper dorsal vertebræ: into the transverse processes of the cervical vertebræ (9), from the 2d to the 6th inclusive. Action, to keep the head erect. Nerves, branches of the cervical.

Trachelo-mastoid (7),—from the transverse processes of the 5 or 6 upper dorsal vertebræ, and the articular processes of the 3 or 4 lower cervical: into the posterior margin of the mastoid process of the temporal bone. Action, to steady the head. Nerves, branches of the cervical.

Spinalis Dorsi,—from the last 2 dorsal and first 2 lumbar spines: into all the remaining dorsal spines. Action, to erect the spinal column. Nerves, branches of the dorsal.

Spinalis Colli,—from the 5th 6th and 7th cervical spines, sometimes from the 1st and 2d dorsal: into the spine of the axis and occasionally into the

- spines of the next two vertebræ below. Action, to steady the neck. Nerves, branches of the cervical. [This muscle is frequently absent.]
- Complexus (8),—by 7 tendons from the tips of the transverse processes of the 7th cervical and 6 or 7 upper dorsal vertebræ, and from the articular processes of the 4th, 5th, and 6th cervical: into the inner depression between the curved lines of the occipital bone. Action, to retract and rotate the head. Nerves, suboccipital, great occipital, and branches of the cervical nerves.
- Biventer Cervicis,—is sometimes described as a part of the complexus; from the transverse processes of 2 to 4 upper dorsal vertebræ: into the superior curved line of the occipital bone Action, as the complexus. Nerves, branches of the cervical.

### FIFTH LAYER.

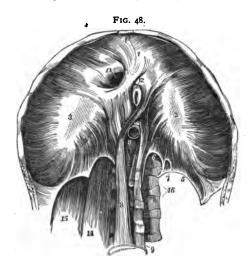

- Semispinalis Dorsi (10),—from the transverse processes of the dorsal vertebræ, from about the 5th to the 11th: into the last 2 cervical and 4 upper dorsal spines. Action, to erect the spinal column. Nerves, branches of the dorsal nerves.
- Semispinalis Colli (11),—from the transverse processes of the 5 or 6 upper dorsal vertebræ: into the 2d, 3d, 4th, and 5th cervical spines. Action, to erect the spinal column. Nerves, branches of the cervical.
- Multifidus Spinæ (16),—from the back of the sacrum, posterior superior spine of the ilium, posterior sacro-iliac ligaments, articular processes of lumbar and 3 or 4 lower cervical vertebræ, and the transverse processes of the dorsal: into the spines of the next 4 vertebræ above. Action, to erect and rotate the spinal column. Nerves, branches of the spinal nerves.
- Rotatores Spinæ,—from the transverse processes of the dorsal vertebræ, from the 2d to the 12th inclusive: each into the lamina of the next dorsal vertebræ above. Action, to rotate the spinal column. Nerves, branches of the posterior dorsal.
- Supra-spinales,—lie on the spinous processes in the cervical region. Nerves, branches of the cervical.
- Inter-spinales,—placed in pairs between the spines of contiguous vertebræ, 6 pairs in the cervical region, 3 in the dorsal, 4 sometimes 6 in the lumbar. Nerves, branches of the posterior spinal.
- Extensor Coccygis,—from the last bone of the sacrum or first of the coccyx: into the lower part of the coccyx, posteriorly. Action, as named. Nerves, branches of the posterior sacral.
- Inter-transversales (18),—placed between the transverse processes of con-

- tiguous vertebræ, 7 in the cervical region, 12 in the dorsal, and 4 in the lumbar. Nerves, branches of the posterior spinal.
- Rectus Capitis Posti'cus Major (13),—from the spine of the axis: into the inferior curved line of the occipital bone and the surface below. Action, to rotate the head. Nerves, suboccipital.
- Rectus Capitis Posti'cus Minor (12),—from the tubercle on the posterior arch of the atlas: into a rough surface between the foramen magnum and the inferior curved line of the occipital bone. Action, to draw the head backward. Nerves, suboccipital.
- Obliquus Capitis Inferior (15),—from the spinous process of the axis: almost horizontally into the transverse process of the atlas. Action, to rotate the atlas and cranium. Nerves, suboccipital.
- Obliquus Capitis Superior (14),—from the transverse process of the atlas. upward and inward into the occipital bone between the curved lines. Action, draws the head backward. Nerves, suboccipital

### MUSCLES OF THE THORAX.

- External Intercostals,—each from the lower border of each rib: into the upper border of the next rib below directed obliquely downward and forward. Action, to raise and evert the ribs in inspiration. Nerves, intercostal.
- Internal Intercostals,—each from the ridge on the inner surface of each rib: into the upper border of the rib below, directed obliquely downward and backward. Action, at sides of thorax to depress the ribs in expiration; anteriorly they raise the costal cartilages. Nerves, intercostals.
- Infra-costales,—obliquely from inner surface of each rib: into the inner surface of the 1st, 2d, or 3d rib below. Action, muscles of inspiration. Nerves, intercostal. [These muscles vary in number and length.]
- Triangularis Sterni,—from the posterior surface of the ensiform cartilage and lower third of the sternum, also from the sternal ends of the costal cartilages of the 3 or 4 lower true ribs: into the lower border and inner surfaces of the 2d, 3d, 4th, 5th, and 6th costal cartilages. Action, to draw down the cartilages in expiration. Nerves, intercostal.
- Levatores Costarum (17 Fig. 47),—each from the transverse process of the 7th cervical and 11 upper dorsal vertebræ: into the upper surface of the next rib below, near its angle. Action, to raise the ribs. Nerves, intercostal.

Diaphragm,—from the ensiform cartilage (4), inner surfaces of 6 or 7 lower ribs, ligamenta arcuata (5), and by its crura (8, 10), from the bodies of the

lumbar vertebræ: into the central or cordiform tendon (2, 3). Action, the great muscle of respiration and expulsion. Nerves, the phrenic, lower intercostals and phrenic plexus of the sympathetic.

OPENINGS OF THE DIA-PHRAGM,—include several small openings and 3 large ones; the Aortic (11), in the middle line posteriorly, and behind the diaphragm; transmits the aorta, vena azygos major, and thoracic

duct. Œsophageal (12), in the muscular structure, transmits the œsophagus and pneumogastric nerves. Opening for the Vena Cava (13) is the highest, and has 4 tendinous margins.

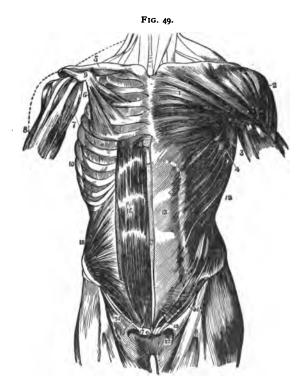

The Right Crus (8) transmits the greater and lesser splanchnic nerves of that side: the Left Crus (10), the greater and lesser splanchnic nerves of the left side and the vena azygos minor.

Descent of the Diaphragm. Its central tendon does not descend during inspiration, being connected with the deep cervical fascia by the fibrous pericardium.

### MUSCLES OF THE ABDOMEN.

External Oblique (12),—from 8 lower ribs by 8 fleshy digitations: into the anterior half of the outer lip of the crest of the ilium, and by a broad aponeurosis (13) into the ensiform cartilage, linea alba, symphysis and spine of the pubes, and the ilio-pectineal line. Its aponeurosis is continuous with that of the pectoralis major above; below it forms Poupart's (14) and Gimbernat's ligaments, and by the separation of its fibres the external abdominal ring (15). Action, to compress the viscera, and flex the thorax on the pelvis, and vice versâ. Nerves, lower intercostal.

Internal Oblique (18),—from the lumbar fascia, the anterior two-thirds of the middle lip of the crest of the ilium, and the outer half of Poupart's ligament: into the cartilages of 4 lower ribs; by its aponeurosis into the linea alba; and leaving an arched border (20) over the spermatic cord, by the conjoined tendon (19) with the transversalis into the pubic crest and the pectineal line. Its aponeurosis splits at the rectus abdominis for its upper three-fourths, one layer passing in front the other behind that muscle, to

unite again at the linea alba; for its lower one-fourth it passes in front of the rectus. *Action*, same as the external oblique. *Nerves*, lower intercostals, ilio-hypogastric, and sometimes from the ilio-inguinal.

Cremaster,—from the inner part of Poupart's ligament, forming a series of loops along the outer side of the spermatic cord: into the crest of the

pubis and the front of the sheath of the rectus. Its origin and insertion is precisely similar to that of the lower fibres of the internal oblique, from which it is derived by the descent of the testicle. Action, to raise the testicle. Nerve, the genital branch of the genito-crural.

Transversalis,—*from* the outer third of Poupart's ligament, the anterior two-thirds of the inner lip of the crest of the ilium, the cartilages of 6 lower ribs, and by its posterior aponeurosis from the spines and transverse processes of the lumbar vertebræ: by its anterior aponeurosis *into* the linea alba, and by the conjoined tendon (19) with the internal oblique, into the pubic crest and the pectineal line. Its anterior aponeurosis passes behind the rectus abdominis for its upper three-fourths, in front of that muscle for its lower one-fourth. Action, as the external oblique. Nerves, as the internal oblique.

LUMBAR FASCIA, or posterior aponeurosis of the transversalis,—divides into 3 leaflets, the anterior and middle being attached to the transverse processes of the lumbar vertebræ, the posterior leaflet to the spines of the lumbar and sacral vertebræ. The anterior and middle leaflets enclose the quadratus lumborum rouscle, the middle and posterior enclose the erector spinæ.

Rectus Abdominis (16),—by 2 tendons from the pubic crest and the ligaments covering the symphysis: into the cartilages of the 5th, 6th, and 7th ribs. It lies in a sheath formed by the aponeuroses of the internal oblique and transversalis muscles for its upper three-fourths, and is crossed by 3 tendinous lines, the Linea Transversa. At its outer border is a similar line placed vertically, the Linea Semilunaris, formed by the aponeurosis of the internal oblique at its point of division. Action, to flex the thorax on the pelvis and vice versa, also to compress the abdominal viscera. Nerves, lower intercostal nerves.

Pyramidalis (17),—lies in front of the rectus, but in the same sheath; arises from the front of the pubic bone and the anterior pubic ligament: into the linea alba, half-way to the umbilicus. Action, a tensor of the linea alba. Nerves, lower intercostal nerves.

Quadratus Lumborum (19 Fig. 47),—from the ilio-lumbar ligament, and the adjacent 2 inches of the crest of the ilium: into one-half of the lower border of the last rib, and the transverse processes of the 4 upper lumbar vertebræ. Action, to flex the thorax laterally on the pelvis and vice versa. Nerves, anterior branches of the last dorsal and 1st lumbar.

The Psoas Magnus the Psoas Parvus and the Iliacus muscles may be con-

sidered deep muscles of the abdomen, but are described with the muscles of the lower extremity.

### MUSCLES OF THE PELVIC OUTLET.

The muscles of this region are situated at the pelvic outlet in the ischiorectal region and the perinæum.

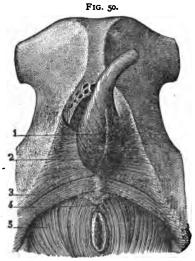

### MUSCLES OF THE ISCHIO-RECTAL REGION.

- Corrugator Cutis Ani,—a thin stratum of involuntary muscular fibre around the anus, radiating from its orifice and serving to raise the skin into ridges around the anal margin.
- External Sphincter Ani (4),—from the tip of the coccyx and superficial fascia: into the tendinous centre of the perinæum. Action, to close the anus. Nerves, inferior hemorrhoidal branch of the internal pudic, also a branch from the anterior division of the 4th sacral.
- Internal Sphincter Ani,—an aggregation of the involuntary circular fibres of the intestine, forming a muscular ring around the rectum about an inch above the margin of the anus. Action, to occlude the anal aperture.
- [A third sphincter, the Sphincter Tertius,—from the sacrum, encircling the rectum about 4 inches above the anus, was demonstrated by Hyrtl, Nelaton and Velpeau, but is denied by other anatomists.]
- Levator Ani (5),—*from* the body and ramus of the pubis posteriorly, the pelvic fascia and the spine of the ischium: *into* the tendinous centre of the perinæum, the sides of the rectum (and vagina), apex of the coccyx, and a fibrous raphé extending from the coccyx to the anus. *Action*, to support the lower end of the rectum and vagina and the bladder, and assist in forming the floor of the pelvis. *Nerves*, branches from the 4th sacral and pudic.
- Coccygeus,—*from* the spine of the ischium and the lesser sacro-sciatic ligament: *into* the margin of the coccyx and the side of the last sacral segment. *Action*, to support the coccyx, and close the outlet of the pelvis posteriorly. *Nerves*, branches from the 4th and 5th sacral.

# MUSCLES OF THE PERINÆUM IN THE MALE.

Transversus Perinæi (3),—/rom the tuberosity of the ischiûm: into the central tendon of the perinæum. Action, to draw tense the central tendon. Nerve, perineal branch of the internal pudic.

Compressor Urethræ (Transversus Perinæi Profundus),—from the junction of the rami of the pubis and ischium: into its fellow of the opposite

side after encircling the membranous portion of the urethræ. Action, the stop-cock muscle. Nerve, perineal branch of the internal pudic.

Accelerator Urinæ (Bulbo-cavernosus) (1),—from the central
tendon of the perinæum and
the median raphé anteriorly:
the fibres spread over the bulb,
corpus spongiosum, corpus cavernosum and the dorsal vessels of the penis. Action, to
accelerate the flow of urine and
erect the penis. Nerve, perineal
branch of the internal pudic.

Erector Penis (2),—from the tuberosity and ramus of the ischium and the crus penis: *into* the crus penis laterally and inferi-

orly. Action, to maintain erection of the penis. Nerve, perineal branch of the internal pudic.

FASCIÆ OF THE PERINÆUM,—are described under the title Perinæum at the end of the book.

#### MUSCLES OF THE PERINAUM IN THE FEMALE.

Transversus Perinæi (3),—from the tuberosity of the ischium internally: into the central point of the perinæum, joining with its fellow of the opposite side. Action, to fix the central tendinous point of the perinæum. Nerve, the perineal branch of the internal pudic.

Sphincter Vaginæ,—surrounds the orifice of the vagina, and is analogous to the accelerator urinæ of the male. Arising *from* the central tendon of the perinæum, its fibres are inserted *into* the corpora cavernosa of the clitoris, a fasciculus crossing over the body of the organ so as to compress the dorsal vein. Action, to diminish the orifice of the vagina. Nerve, perineal branch of the internal pudic.

Erector Clitoridis,—from the tuberosity and ramus of the ischium internally: into the crus clitoridis by an aponeurosis. Action, to erect the

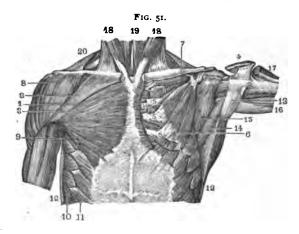

clitoris by retarding the return of its blood supply. Nerve, perineal branch of the internal pudic.

Compressor Urethræ,—from the margin of the descending ramus of the pubic bone: *into* its fellow in front of the urethra and *into* the wall of the vagina behind the urethra. *Action*, as indicated by its name. *Nerve*, perineal branch of the internal pudic.

#### MUSCLES OF THE UPPER EXTREMITY.

MUSCLES OF THE THORACIC REGION.

Pectoralis Major (1, 2, 3),—jrom the sternal half of the clavicle, by an aponeurosis from the front of the sternum as low as the 6th or 7th rib, the cartilages of all the true ribs (5), and the aponeurosis of the external oblique: the fibres converge, cross and are inserted by a flat tendon (4)' into the external bicipital ridge of the humerus, having crossed the bicipital

groove. Action, to draw the arm forward and downward; also to elevat the ribs in forced inspiration. Nerves, anterior thoracic.

Pectoralis Minor (6),—/rom the 3d, 4th, and 5th ribs, and the intercostal aponeurosis: into the coracoid process of the scapula. Action, to depress the point of the shoulder, also to elevate the ribs in forced inspiration. Nerves, anterior thoracic.

Subclavius (7),—from the cartilage of the 1st rib: into a deep groove on the 7

under surface of the clavicle. Action, to draw the clavicle downward. Nerve, a branch from the 5th cervical.

Serratus Magnus,—by 9 digitations (10) from the 8 upper ribs (the 2d rib having 2) and from the intercostal aponeurosis: into the whole length of the ventral aspect of the vertebral border of the scapula. Action, to elevate the ribs in inspiration, also to raise the point of the shoulder. In the lower animals it is the great sling-muscle, slinging the body between the upper extremities. Nerve, posterior thoracic.

## MUSCLES OF THE SHOULDER AND ARM.

- Deltoid (8),—*from* the outer third of the anterior and superior surfaces of the clavicle, the outer margin and upper surface of the acromion, and the lower border of the spine of the scapula: *into* a prominence on the outer side of the shaft of the humerus, about its middle. *Action*, to raise the arm. *Nerve*, circumflex.
- Subscapularis (15),—from the inner two-thirds of the subscapular fossa: into the lesser tuberosity of the humerus. Action, to rotate the head of the humerus inward. Nerves, subscapular.
- Supraspinatus,—*from* the inner two-thirds of the supraspinous fossa and the fascia covering the muscle: *into* the upper facet of the greater tuberosity of the humerus. *Action*, to support the shoulder-joint, and to raise the arm. *Nerve*, suprascapular.
- Infraspinatus,—/rom the inner two-thirds of the infraspinous fossa and the covering fascia: into the middle facet on the greater tuberosity of the humerus. Action, to rotate the humerus outward. Nerve, suprascapular.
- Teres Minor (14),—/rom the upper two-thirds of the dorsal surface of the axillary border of the scapula: into the lowest facet on the greater tuberosity of the humerus, and the bone below. Action, to rotate the humerus outward. Nerve, circumflex.
- Teres Major,—/rom the dorsal aspect of the inferior angle of the scapula: into the internal bicipital ridge of the humerus. Action, to assist the latissimus dorsi Nerve, subscapular.
- Coraco-brachialis (11),—from the apex of the coracoid process (2) of the scapula: into a ridge on the inner side of the shaft of the humerus, about its middle. Action, elevates the humerus forward and inward. Nerve, musculo-cutaneous, which perforates this muscle.

Biceps (15) (biceps flexor cubiti),—Long head (8) from the upper margin of

the glenoid cavity; short head (12) from the apex of the coracoid process (2), in common with the coraco-brachialis: into the back of the tuberosity of the radius, and the fascia (20) of the forearm. Action, to flex and supinate the forearm, and to make tense its fascia. Nerve, the musculocutaneous.

Brachialis Anti'cus (17),—from the lower half of the shaft of the humerus anteriorly and laterally, embracing the insertion of the deltoid (9): into the base of the coronoid process (19) of the ulna. Action, a flexor of the forearm. Nerves, musculocutaneous and musculo-spiral.

Triceps (16) (triceps extensor cubiti),—by three heads, the outer and inner from the posterior surface of the shaft of the humerus, the outer above, the inner below the musculo-spiral groove; the middle or long head from a depression below the glenoid cavity of the scapula: by a common tendon into the upper end of the olecranon process of the ulna. Action, to extend the forearm. Nerve, musculo-spiral.

Subanconeus,—*from* the humerus above the olecranon fossa: *into* the posterior ligament of the elbow-joint. *Action*, probably a tensor of the ligament. *Nerve*, musculo-spiral.

## MUSCLES OF THE FOREARM.

Muscles of the Forearm, arranged in groups of 5 and 3. (Pancoast.)
Anteriorly, 5 flexors, 2 pronators, 1 tensor of palmar fascia:—

Flexor Carpi Radialis.

Pronator Radii Teres.

Flexor Carpi Ulnaris.

Pronator Quadratus.

Flexor Longus Pollicis.

Palmaris Longus.

Flexor Sublimis Digitorum Perforatus Manis.

Flexor Projundus Digitorum Perjorans Manis

POSTERIORLY 12 muscles in 4 sets of threes:-

Supinator Longus. Extensor Indicis.

Extensor Carpi Radialis Longior. Extensor Communis Digitorum.

Extensor Carpi Radialis Brevior. Extensor Minimi Digiti.

Extensor Ossis Metacarpi Pollicis. Extensor Carpi Ulnaris.

Extensor Brevis Pollicis.

Anconeus.

Extensor Longus Pollicis. Supinator Brevis.

Pronator Radii Teres (4),—by 2 heads, one *from* above the internal condyle of the humerus, the common tendon, fascia, and the intermuscular septum; the other from the inner side of the coronoid process of the ulnainto a rough ridge on the outer side of the shaft of the radius, about its middle. Action, to pronate the hand. Nerve, median, which passes between the 2 heads of the muscle.

Flexor Carpi Radialis (5),—from the internal condule of the humerus by the common tendon, the fascia, and the intermuscular septa: into the base of the metacarpal bone of the index finger. Action, to flex the wrist. Nerve, median.

Palmaris Longus (6),—Irom the same origin as the flexor carpi radialis: into the annular ligament and the palmar fascia (9). Action, to make the palmar fascia tense. Nerve, median.

Flexor Carpi Ulnaris (8),—by 2 heads, one from the inner condyle of the humerus by the common tendon, the other from the inner margin of the olecranon, the upper two-thirds of the posterior border of the ulna, and the intermuscular septum: into the pisiform bone, the annular ligament, and the 5th metacarpal and unciform bones. Action, to flex the wrist. Nerve, ulnar.

Flexor Sublimis Digitorum (Perforatus) (7),—by 3 heads, one from the inner condyle of the humerus by the common tendon, the internal lateral ligament, and the intermuscular septum; the second from the inner side of the coronoid process of the ulna; the third from the oblique line of the radius: into the lateral margins of the second phalanges by 4 tendons which are split for the passage of the deep flexor tendons. Action, to flex the second phalanges. Nerve, median.

Flexor Profundus Digitorum (Perforans),—from the upper three-fourths of the shaft of the ulna, a depression on the inner side of the coronoid process, and the interosseous membrane: into the bases of the last phalanges, by 4 tendons which perforate the tendons of the superficial flexor. Action, to flex the phalanges. Nerves, ulnar, anterior interosseous branch of the median.

Flexor Longus Pollicis,—from the upper two-thirds of the shaft of the

radius and the interosseous membrane: *into* the base of the last phalanx of the thumb, which it flexes. *Nerve*, anterior interosseous branch of the median.

Pronator Quadratus,—jrom the oblique line on the lower fourth of the ulna, and the anterior border of the ulna: into the lower fourth of the anterior border of the shaft of the radius. Action, to pronate the hand. Nerve, anterior interosseous branch of the median.

Supinator Longus (13),—from the upper two-thirds of the external condyloid ridge of the humerus, and the intermuscular septum: into the base of the styloid process of the radius. Action, to supinate the hand. Nerve, musculo-spiral.

Extensor Carpi Radialis Longior (e),—from the lower third of the external condyloid ridge of the humerus, and the intermuscular septum: into the base of the metacarpal bone of the index finger (g), on its radial side. Action, to extend the wrist. Nerve, musculo-spiral.

Extensor Carpi Radialis Brevior (f),—from the external condyle of the humerus by the common tendon, the external lateral ligament, and the intermuscular septa: into the radial side of the base of the 3d metacarpal bone (g). Action, to extend the wrist. Nerve, posterior interosseous.

Extensor Communis Digitorum (h),—from the external condule of the humerus by the common tendon, the deep fascia, and the intermuscular septa: into the 2d and 3d phalanges of all the fingers, by 3 tendons, one of which divides into two. Action, to extend the fingers. Nerve, posterior interosseous.

Extensor Minimi Digiti (i),—from the common tendon and the intermuscular septa: into the 2d and 3d phalanges of the little finger, with the tendon derived from the common extensor. Action, as named. Nerve, posterior interosseous.

Extensor Carpi Ulnaris (j),—from the common tendon, the middle third

of the posterior border of the ulna, and the deep fascia of the forearm: into the base of the 5th metacarpal bone. Action, to

FIG. 54.

Anconeus (k),—/rom the external condyle of the humerus, posteriorly: into the side of the olecranon, and upper fourth of the posterior surface of the shaft of the ulna. Action, to extend the forearm. Nerve, the musculo-spiral.

extend the wrist. Nerve, posterior interosseous.

Supinator Brevis—from the external condyle of the humerus, the external lateral and orbicular ligaments and an oblique line on the ulna: into the inner surface of the neck of the radius, the outer edge of its bicipital tuberosity, and the oblique line. Action, to supinate the hand. Nerve, posterior interosseous, which pierces it.

Extensor Ossis Metacarpi Pollicis (14),—from the posterior surfaces of the shafts of the radius and ulna, and the interosseous membrane: into the base of the metacarpal bone of the thumb. Action, to extend the thumb. Nerve, posterior interosseous.

Extensor Brevis Pollicis (Extensor Primi Internodii Pollicis) (n),—from the posterior surface of the shaft of the radius and the interosseous membrane: into the base of the 1st phalanx of the thumb. Action, to extend the thumb. Nerve, posterior interosseous.

Extensor Longus Pollicis (Extensor Secundi Internodii Pollicis) (m),—from the shaft of the ulna

posteriorly and the interosseous membrane: into the base of the last phalanx of the thumb. Action, to extend the thumb. Nerve, posterior interosseous.

Extensor Indicis,—from the shaft of the ulna posteriorly and the interosseous membrane: into the 2d and 3d phalanges of the index finger with the tendon of the common extensor. Action, to extend the index finger. Nerve, posterior interosseous.

## FASCIÆ OF THE HAND.

Anterior Annular Ligament,—from the pisiform and unciform bones: to the tuberosity of the scaphoid and the ridge on the trapezium. Inserted

into its anterior surface are parts of the tendons of the palmaris longus and the flexor carpi radialis, and beneath it pass the tendons of the superficial and deep flexors of the fingers and the flexor longus pollicis, also the median nerve. It is continuous with the palmar fascia and the deep fascia of the forearm.

POSTERIOR ANNULAR LIGAMENT (0),—from the ulna, cuneiform and pisiform bones: to the margin of the radius and the ridges on its posterior surface. It has 6 canals for the passage of the extensor tendons, each lined by a synovial membrane. It is continuous with the deep fascia of the forearm.

DEEP PALMAR FASCIA,—ensheathes the muscles of the hand, and divides into 4 slips for the four fingers, each slip dividing and forming tendinous arches for the passage of the flexor tendons of the fingers.

## MUSCLES OF THE HAND.

- Abductor Pollicis (11),—from the ridge of the trapezium, the tuberosity of the scaphoid, and the annular ligament: into the radial side of the base of the 1st phalanx of the thumb. Action, to draw the thumb from the median line. Nerve, median.
- Opponens Pollicis,—from the palmar surface of the trapezium and the annular ligament: into the radial side of the metacarpal bone of the thumb, for its whole length. Action, as a flexor ossis metacarpi pollicis. Nerve, median.
- Flexor Brevis Pollicis (12),—the outer portion from the lower border of the annular ligament, the inner and deeper portion from the ulnar side of the 1st metacarpal bone: *into* both sides of the base of the 1st phalanx of the thumb, by two tendons, each having a sesamoid bone in it. Action, to flex the thumb. Nerves, median and ulnar.
- Adductor Obliquus Pollicis,—from the os magnum, the bases of the 2nd and 3rd metacarpal bones, the anterior carpal ligaments and the sheath of the tendon of the flexor carpi radialis: into the inner side of the base of the 1st phalanx of the thumb, having a sesamoid bone in the tendon of insertion. Action, to draw the thumb toward the median line. Nerve, ulnar.
- Adductor Transversus Pollicis,—from the lower two-thirds of the metacarpal bone of the middle finger: into the ulnar side of the base of the 1st phalanx of the thumb. Action, as the preceding muscle. Nerve, ulnar.
- [The above-mentioned 5 muscles of the thumb occupy the radial side of the hand and form the *Thenar Eminence*: the first 4 of the following-mentioned muscles occupy the ulnar side of the hand and form the *Hypothenar Eminence*.]

- Palmaris Brevis (10),—/rom the annular ligament and palmar fascia: into the skin on the inner border of the palm of the hand Action, to corrugate the skin of the hand. Nerve ulnar.
- Abductor Minimi Digiti,—*from* the pisiform bone and the tendon of the flexor carpi ulnaris: *into* the ulnar side of the base of the 1st phalanx of the little finger and the aponeurosis of the extensor minimi digiti. *Action*, as indicated by its name. *Nerve*, ulnar.
- Flexor Brevis Minimi Digiti,—/rom the hook of the unciform bone and the annular ligament: into the base of the 1st phalanx of the little finger, with the preceding muscle. Action, as named. Nerve, ulnar.
- Opponens Minimi Digiti,—/rom the unciform bone and the annular ligament: into the whole ulnar margin of the 5th metacarpal bone. Action, a flexor of the 5th metacarpal bone. Nerve, ulnar.
- Lumbricales 4,—from the tendons of the deep flexor: into the expanded tendons of the common extensor on the dorsi of the phalanges. Action, probably to flex the 1st phalanges. Nerves, median and ulnar.
- Dorsal Interossei 4,—by 2 heads from the adjacent sides of the metacarpal bones: into the bases of the 1st phalanges of the index, middle, and ring fingers, the middle finger having two. Action, abductors of the fingers from the median line. Nerve. ulnar.
- Palmar Interossei 3,—*from* the palmar surfaces of the 2d, 4th, and 5th metacarpal bones: *into* the bases of the 1st phalanges of the same fingers.

  Action, adductors of the fingers Nerve, ulnar

# MUSCLES OF THE LOWER EXTREMITY.

MUSCLES AND FASCIÆ OF THE ILIAC REGION.

ILIAC FASCIA,—is an aponeurotic layer which lines the back of the abdominal cavity and covers the psoas and iliacus muscles throughout their whole extent. It is attached above to the ligamentum arcuatum internum, internally by arched processes to the bodies of the vertebræ, also to the sacrum and the brim of the true pelvis; externally it is continuous with the lumbar fascia above and is attached to the whole length of the inner border of the crest of the ilium; below it is continuous with the fascia transversalis and the pubic part of the fascia lata of the thigh, is intimately connected to Poupart's ligament, and is prolonged backward and inward therefrom as a band, the *Ilio-pectineal Ligament*, to the ilio-pectineal eminence. It descends behind the femoral vessels into the thigh, forming the posterior wall of the femoral sheath.

- Psoas Magnus (11),—from the bodies, transverse processes, and intervertebral substances of the last dorsal and all the lumbar vertebræ: into the lesser trochanter of the femur, by a common tendon with the iliacus. Action, to flex the thigh upon the pelvis, and when the femur is fixed to bend the trunk forward. Nerves, anterior branches of the 2nd and 3rd lumbar.
- Psoas Parvus,—*from* the bodies of the last dorsal and first lumbar vertebræ and the intervertebral substance: *into* the ilio-pectineal eminence and the iliac fascia. *Action*, when present it is a tensor of the iliac fascia. *Nerve*, anterior branch of the 1st lumbar.
- Iliacus (10),—from the iliac fossa, inner margin of the iliac crest, ilio-lumbar ligament, base of the sacrum, anterior spinous processes of the ilium and the notch between them, and from the capsule of the hip-joint: into the outer side of the tendon of the psoas magnus. Action, the same as that of the psoas magnus. Nerve, anterior crural.

#### MUSCLES AND FASCIÆ OF THE THIGH.

- SUPERFICIAL FASCIA,—forms a continuous covering over the whole thigh in two layers, between which lie the superficial vessels and nerves. The superficial layer is continuous above with the superficial fascia of the abdomen. The deep layer is fibrous and very thin; it covers the saphenous opening in the fascia lata (see below), where it is perforated for the internal saphenous vein and numerous vessels, and is therefore called the *Cribriform Fascia* in this situation. It forms one of the coverings of a femoral hernia.
- FASCIA LATA,—the deep fascia of the thigh, extends from Poupart's ligament to the prominent points around the knee-joint, and from the margin of the sacrum and coccyx around the limb to the pubic arch and pectineal line. It sends two strong intermuscular septa down to the linea aspera, and contains the Saphenous Opening, which is formed by the reflected margins of its pubic and iliac portions. The structure named Poupart's Ligament is made by the knife, and is only the line of junction between the aponeurosis of the external oblique muscle and the fascia lata; extending from the anterior superior spine of the ilium to the spine of the pubic bone.
- Tensor Vaginæ Femoris (4),—/rom the anterior part of the outer lip of the iliac crest, the anterior superior spinous process and part of the notch below it, also from the fascia covering the gluteus medius: into the fascia lata, between its two layers, about one-fourth down the outer side of the thigh. Action, a tensor of the fascia lata. Nerve, superior gluteal

Sartorius (5),-from the anterior superior spine of the ilium (2) and half of

the notch below it: *into* the upper internal surface of the shaft of the tibia. *Action*, to flex and cross the legs. *Nerve*, anterior crural.

[Quadriceps Extensor,—including the 4 remaining muscles on the front of the thigh,—the rectus femoris, vastus externus, vastus internus, and the crureus. Its tendon is inserted into the patella. Action, the great extensor of the leg. Nerve, anterior crural.]

Rectus Femoris (6),—by two tendons, the Straight from the anterior inferior spine of the ilium, the Reflected from a groove above the brim of the acetabulum: into the patella by a flattened tendon (9) which is common to this and the next 3 muscles. Action, to extend the leg. Nerve, anterior crural.

Vastus Externus (7),—from the anterior border of the great trochanter and part of the linea aspera of the femur: into the outer border of the patella, by a flat tendon which blends with the great extensor tendon. Action, to extend the leg. Nerve, anterior crural.

Vastus Internus (8),—from the anterior intertrochanteric line, the spiral line, the linea aspera, the internal supracondylar line, the tendon of the adductor magnus and the intermuscular septum: into the inner border of the patella and the great extensor tendon. Action, to extend the leg. Nerve, anterior crural

Crureus,—from the upper two-thirds of the shaft of the femur and the intermuscular septum: into the great extensor tendon. Action, to extend the leg Nerve, anterior crural. This muscle and the vastus internus appear to be inseparably united, but they can be separated.

Subcrureus,—often blended with the crureus: from the lower part of the shaft of the femur anteriorly;—into the capsular ligament behind the patella. Action, to draw up the capsular ligament. Nerve, anterior crural.

Gracilis (15),—from the margin of the symphysis and the anterior half of the pubic arch: into the inner surface of the shaft of the tibia below the

tuberosity. Action, to flex the leg and rotate it inward, also to adduct the thigh. Nerve, obturator.

Pectineus (12),—from the ilio-pectineal line, and the bone in front thereof, also from the fascia covering the muscle: into the rough line extending from the trochanter minor to the linea aspera. Action, to adduct the thigh and rotate it outward. Nerves, accessory obturator, anterior crural.

Adductor Longus (13),—from the front of the os pubis: into the middle third of the linea aspera. Action, to adduct the thigh powerfully. Nerve, obturator.

Adductor Brevis,—/rom the body and descending ramus of the os pubis;

into the upper part of the linea aspera. Action, to adduct the thigh. Nerve, obturator.

Adductor Magnus (14),—from the descending ramus of the os pubis, the ramus of the ischium, and the outer margin and under surface of the tuberosity of the ischium: into the rough line leading from the great trochanter to the linea aspera, the whole length of the linea aspera, and by a tendon into the tubercle on the inner condyle of the femur. Action, to adduct the thigh and rotate it outward. Nerves, obturator and great sciatic. This muscle is pierced by 4 apertures for the 3 superior perforating and the profunda arteries, and about the lower one-third of its insertion an angular interval is left therein, the lower opening of Hunter's canal, for the passage of the femoral vessels into the popliteal space.

## MUSCLES OF THE HIP.

Giuteus Maximus (b),—jrom the superior curved line of the ilium, the crest behind it, the last piece of the sacrum, the side of the coccyx, the great sacro-sciatic ligament, the aponeurosis of the erector spinæ and the fascia covering the gluteus medius: into the fascia lata and the rough line leading from the great trochanter to the linea aspera. Action, to extend and abduct the thigh

and rotate it outward, also to maintain the trunk erect. Nerves, inferior gluteal from the sacral plexus.

Gluteus Medius (a),—from the ilium between the superior and middle

FIG. 56.

curved lines, the crest between them and the fascia of the part: into the oblique lines on the great trochanter. Action, its posterior fibres rotate the thigh outward, its anterior fibres rotate inward. It also abducts the thigh and draws it forward, and assists to maintain the trunk erect. Nerve, superior gluteal.

Gluteus Minimus (8),—from the ilium between the middle and inferior curved lines, and the margin of the great sacro-sciatic notch: into the anterior border of the great trochanter. Action, to rotate the thigh inward, also to abduct and draw it forward, and to maintain the trunk erect. Nerve, superior gluteal.

Pyriformis (9),—by 3 digitations from the front of the sacrum, from the margin of the great sacro-sciatic foramen and the great sacro-sciatic ligament: *into* the upper border of the great trochanter (7), having passed through the great sacro-sciatic foramen. *Action*, an external rotator of the thigh. *Nerves*, first and second sacral.

Obturator Internus (11),—from the posterior bony margin of the obturator foramen and the inner surface of the obturator membrane: into the great

trochanter (7), passing through the lesser sacro-sciatic foramen. Action, an external rotator of the thigh. Nerves, 5th lumbar, 1st and 2nd sacral.

Gemellus Superior (10), from the outer surface of the spine of the ischium: into the great trochanter, being blended with the tendon of the obturator internus. Action, an external rotator of the thigh. Nerves, 5th lumbar, 1st and 2nd sacral.

Gemellus Inferior (12), from the tuberosity of the ischium: into the tendon of the obturator internus and the great trochanter. Action, an external rotator of the thigh. Nerves, 5th lumbar, 1st sacral.

Quadratus Femoris (13),—/rom the tuberosity of the ischium: into the upper part of the linea quadrata on the trochanter major posteriorly.

Action, an external rotator of the thigh. Nerves, 5th lumbar, 1st sacral

Obturator Externus,—from the anterior inner bony margin of the obturator foramen, and the inner two-thirds of the anterior surface of the obturator membrane: into the digital fossa of the femur. Action, an external rotator of the thigh. Nerve, obturator.

Biceps (16),—by 2 heads, the Long Head (d) from the tuberosity of the ischium posteriorly, the Short Head (e) from the outer lip of the linea aspera, and the intermuscular septum: into the outer side of the head of the fibula; its tendon embracing the external lateral ligament of the knee-joint and forming the Outer Hamstring, the tendons of the semi-tendinosus, semi-membranosus, gracilis and sartorius forming the Inner Hamstring. Action, to flex the leg and rotate it outward. Nerve, great sciatic.

Semi-tendinosus (f),—from the tuberosity of the ischium by a tendon (4) common to it and the long head of the biceps, and from the adjacent aponeurosis: into the shaft of the tibia at its upper and inner surface, its tendon curving around the inner tuberosity. Action, to flex the leg upon the thigh. Nerve, great sciatic.

Semi-membranosus (g),—from the tuberosity of the ischium above the origin of the above-named two muscles: into the inner tuberosity of the tibia; its tendon of insertion giving off fibrous expansions one to the outer condyle of the femur forming part of the posterior ligament of the knee-joint, another to the fascia covering the popliteus muscle, and fibres to the internal lateral ligament of the joint. Action, to flex the leg, and rotate it inward. Nerve, great sciatic.

External Rotators of the Hip-joint are 13½,—the 3 adductors, pyriformis, 2 obturators, 2 gemelli, quadratus femoris, pectineus, psoas magnus, iliacus, sartorius, and posterior half of the gluteus medius.

Internal Rotators of the Hip-joint are  $2\frac{1}{2}$ ,—the tensor vaginæ femoris, gluteus minimus, and the anterior half of the gluteus medius.

#### MUSCLES OF THE LEG.

Muscles of the leg arranged in groups of threes. (Pancoast.)

Tibialis Anticus. Tibialis Posticus.

Extensor Proprius Hallucis. Flexor Longus Hallucis.

Extensor Longus Digitorum. Flexor Longus Digitorum.

Gastrocnemius. Peroneus Longus.

Gastrocnemius. Peroneus Longus.
Soleus. Peroneus Brevis.

Plantaris. Popliteus. Peroneus Tertius.

Tibialis Anti'cus (3),—jrom the outer tuberosity and upper two-thirds of the shaft of the tibia externally, the interosseous membrane, deep fascia, and intermuscular septum; through the inner capal in the anterior annular

ligament; into the inner and plantar surface of the internal cuneiform bone, and the base of the 1st metatarsal. Action, to flex the tarsus on the leg, and elevate the inner border of the foot. Nerve, anterior tibial.

Extensor Proprius Hallucis (5),—*from* the middle two-fourths of the fibula anteriorly and the interosseous membrane, through the 2d canal in the anterior annular ligament: *into* the base of the last phalanx of the great toe. *Action*, to extend that toe. *Nerve*, anterior tibial.

Extensor Longus Digitorum (4),—from the outer tuberosity of the tibia, the upper three-fourths of the shaft of the fibula anteriorly, interosseous membrane, deep fascia, and intermuscular septa: into the 2d and 3d

Fig. 58.

phalanges of the 4 lesser toes, by 4 tendons which pass over the dorsum of the foot from the outer canal in the anterior annular ligament. Action, to extend the lesser toes. Nerve, anterior tibial.

Peroneus Tertius (6),—from the outer lower fourth of the fibula, interosseous membrane and intermuscular septum: into the base of the 5th metatarsal bone. This muscle is a part of the lastnamed, and passes through the same canal in the annular ligament. Action, to flex the tarsus. Nerve, anterior tibial.

Gastrocnemius,—by 2 heads (9, 10), from the condyles of the femur, and the supra-condyloid ridges: unites with the tendon of the soleus to form the tendo Achillis, into the posterior tuberosity of the os calcis. Action, to extend the foot. Nerve, internal popliteal.

Soleus,—from the head and upper third of the shaft of the fibula posteriorly, the oblique line of the tibia, and the tendinous arch: unites with the tendon of the gastrocnemius as the tendo Achillis (see above). Action, to extend the foot. Nerves, internal popliteal, posterior tibial.

Plantaris,—/rom the outer bifurcation of the linea aspera and the posterior ligament of the knee-joint: by a very long, delicate tendon into the

posterior surface of the os calcis. Action, to extend the foot. Nerve, internal popliteal.

Popliteus (6 Fig. 59),—from a depression on the external condyle of the femur, and the posterior ligament of the knee-joint: into the inner two-thirds of the triangular surface on the shaft of the tibia (2) posteriorly and above the oblique line. Action, to flex the leg. Nerve, internal popliteal.

Flexor Longus Hallucis (9),—from the lower two-thirds of the shaft of the fibula internally, the interosseous membrane, fascia, and intermuscular septum, its tendon passing through grooves in the tibia, astragalus and os calcis: into the base of the last phalanx of the great toe.

Action, to flex the great toe. Nerve, posterior tibial.

Flexor Longus Digitorum (7),—from the shaft of the tibia posteriorly and below the oblique line; its tendon passing behind the inner malleolus in a groove (13) with the tibialis posticus: into the bases of the last phalanges of the lesser toes by 4 tendons which perforate the tendons of the flexor brevis digitorum. Action, to flex the phalanges and extend the foot. Nerve, posterior tibial.

**Tibialis Posti'cus** (8),—by two processes between which pass the anterior tibial vessels, *from* the upper half of shaft of the tibia posteriorly, the upper two-thirds of the shaft of the fibula internally, the interosseous membrane, deep fascia, and intermuscular septa; its tendon passes behind the inner malleolus in a groove (13) with the long flexor: *into* the tuberosity of the scaphoid and internal cuneiform bones. *Action*, to extend the tarsus and invert the foot. *Nerve*, posterior tibial.

Peroneus Longus (10),—from the head of the fibula, and the upper two-thirds of its shaft externally, the deep fascia and intermuscular septa, passes behind the outer malleolus in a groove with the peroneus brevis, through a groove in the cuboid bone: into the outer side of the base of the metatarsal bone of the great toe and the internal cuneiform bone, having crossed the sole of the foot obliquely. Action, to extend and evert the foot. Nerve, musculo-cutaneous branch of the

extend and evert the foot. *Nerve*, musculo-cutaneous branch of the external popliteal.

Peroneus Brevis (11),—from the lower two-thirds of the shaft of the fibula externally and the intermuscular septa: its tendon passes behind the external malleolus in a groove with the long peroneal, into the dorsum of the

FIG. 59.

base of the 5th metatarsal bone. Action, to extend the foot. Nerve, musculo-cutaneous branch of the external popliteal.

#### FASCIÆ OF THE FOOT.

ANTERIOR ANNULAR LIGAMENT (12 Fig. 58),—consists of vertical and horizontal portions, is attached to the lower ends of the fibula and tibia, the os calcis and the plantar fascia. It contains sheaths lined by synovial membranes for the tendons of the extensor muscles, (that of the extensor proprius hallucis passing beneath it), as also the anterior tibial vessels and

INTERNAL ANNULAR LIGAMENT,—from the inner malleolus to the os calcis, converting 4 bony grooves into canals lined by synovial membranes for the flexor tendons and the posterior tibial vessels and nerve.

EXTERNAL ANNULAR LIGAMENT,—from the outer malleolus to the os calcis, binding down the peronei tendons in one synovial sac.

PLANTAR FASCIA,—the densest in the body, divided into a central and two lateral portions, and attached to the inner tuberosity of the os calcis, divides into 5 processes, 1 for each toe, and several intermuscular septa.

DORSAL FASCIA,—is a thin membranous layer continuous above with the anterior margin of the annular ligament, and becoming gradually lost opposite the heads of the metatarsal bones, and on each side blending with the plantar fascia. It forms a sheath for the tendons on the dorsum of the foot.

## MUSCLES OF THE FOOT.

Extensor Brevis Digitorum (11 Fig. 58),—the only muscle on the dorsum of the foot, arises from the os calcis externally, the calcaneo-astragaloid and the anterior annular ligaments:—by 4 tendons, 1 into the 1st phalanx of the great toe, and the others into the outer sides of the long extensor tendons of the 2d, 3d, and 4th toes. Action, to extend the toes. Nerve, anterior tibial.

Muscles on the sole of the foot number 19; arranged by layers:-

1st Laver.

3d Layer.

Abductor Hallucis.

Flexor Brevis Hallucis.

Flexor Brevis Digitorum. Adductor Obliquus Hallucis.

Abductor Minimi Digiti. Flexor Brevis Minimi Digiti.

Pancoast's Triangle, the lowest Adductor Transversus Hallucis. ) in the body.

2d Layer.

4th Laver.

Flexor Accessorius. Lumbricales. 4.

Interossei (4 Dorsal, 3 Plantar).

Abductor Hallucis,-from the inner tubercle of the os calcis, the internal annular ligament, plantar fascia, and intermuscular septum: into the inner

side of the base of the 1st phalanx of the great toe. Action, to abduct the great toe. Nerve, internal plantar.

Plexor Brevis Digitorum,—from the inner tubercle of the os calcis (11), the plantar fascia and intermuscular septa: into the sides of the 2d pha-

langes of the lesser toes by 4 tendons (5) which are perforated for the long flexor tendons (2). Action, to flex the lesser toes. Nerve, internal plantar.

Abductor Minimi Digiti,—from the tubercles and under surface of the os calcis (11), the plantar fascia and the intermuscular septum: into the base of the 1st phalanx of the little toe with the tendon of its short flexor. Action, to abduct the little toe. Nerve, external plantar.

Flexor Accessorius (1),—by 2 heads, from the os calcis and the long plantar ligament: into the tendon of the flexor longus digitorum. Action, accessory flexor of the toes. Nerve, external plantar

Lumbricales (4), four, from the long flexor tendons: each into the dorsum of the 1st phalanx of the corresponding toe. Action, accessory flexors of the toes. Nerves, internal plantar to the innermost lumbrical, external plantar to the other three.

Flexor Brevis Hallucis (7),—from the cuboid and external cuneiform bones, and the prolonged tendon of the tibialis posticus: into both sides of the

base of the 1st phalanx of the great toe, by 2 portions, of which one blends with the abductor hallucis, the other with the adductor obliquus hallucis. *Action*, to flex the great toe. *Nerve*, internal plantar.

Adductor Obliquus Hallucis,—from the tarsal ends of the three middle metatarsal bones, and the sheath of the tendon of the peroneus longus: into the base of the 1st phalanx of the great toe, externally. Action, to adduct the great toe. Nerve, external plantar.

Flexor Brevis Minimi Digiti (6),—from the base of the 5th metatarsal bone (9) and the sheath of the tendon of the peroneus longus: into the base of the 1st phalanx of the little toe externally. Action, to flex the little toe. Nerve, external plantar.

Adductor Transversus Hallucis (Transversus Pedis),—*from* the inferior metatarso-phalangeal ligaments of the three outer toes and the transverse

ligament of the metatarsus: *into* the outer side of the 1st phalanx of the great toe, blending with the tendon of the adductor obliquus hallucis. *Action*, to adduct the great toe. *Nerve*, external plantar.

Dorsal Interossei 4,—each by two heads from the adjacent sides of two metatarsal bones: into the base of the 1st phalanx of the corresponding toe. Action, to abduct the toes. Nerve, external plantar.

Plantar Interossei 3,—from the shafts of the 3d, 4th, and 5th metatarsal bones: into the bases of the 1st phalanges of the same toes. Action, to adduct the toes toward the median line. Nerve, external plantar.

# THE BLOOD-VASCULAR SYSTEM.

## THE HEART.

The Pericardium is a conical membranous sac, containing the heart and the roots of the great vessels. It lies behind the sternum and between the pleuræ, its apex upward, its base attached to the central tendon of the diaphragm. It is composed of an outer fibrous coat, and an inner serous one; the former is prolonged on the outer surfaces of the great vessels, except the inferior vena cava, and becomes continuous with the deep layer of the cervical fascia; the latter consists of a parietal layer, lining the inner surface of the fibrous coat, and a visceral layer, which is reflected over the heart and vessels. The serous portion secretes a thin fluid, about 1 drachm in quantity normally, for the lubrication of its surfaces. Arteries, are derived from the internal mammary and its musculo-phrenic branch, and from the descending thoracic aorta. Nerves, are branches from the vagus, the phrenic and the sympathetic.

The Endocardium is a thin, smooth, transparent membrane, which lines the internal surface of the heart; assisting by its reduplications in forming the valves, and being continuous with the lining membrane of the great blood-vessels.

The Heart is a hollow muscular organ, conoidal in shape, placed obliquely in the chest between the lungs, base upward, apex to the left and front, corresponding to the space between the 5th and 6th costal cartilages,  $\frac{3}{4}$  inch inside of and  $1\frac{1}{2}$  inch below the left nipple. In the adult its size is about 5 inches by  $3\frac{1}{2}$  by  $2\frac{1}{2}$ , and from 10 to 12 oz. in weight in the male, 8 to 10 oz. in the female.

The Cavities of the Heart are 4 in number, an auricle and a ventricle on each side of the heart; the cavities on one side being separated from those of the other side by a longitudinal muscular septum. The division into 4 cavities is indicated on the external surface of the organ by grooves, named,

from their contiguous cavities, the auriculo-ventricular groove transversely, and the inter-ventricular grooves longitudinally.

Structure of the Heart. The muscular fibres forming the heart take origin from four fibrous rings at the auriculo-ventricular and aortic openings. The fibres of the auricles are arranged in two layers, a superficial and a deep one, the latter having looped fibres and annular fibres. In the ventricles the fibres are also superficial and deep, the latter being arranged circularly, the former spirally, coiling inward at the apex of the heart into a whorl-like form, the *vortex*.

Vessels and Nerves. The Arteries are the right and left coronary from the aorta. The Veins accompany the arteries and terminate in the right auricle. The Lymphatics terminate in the thoracic and right lymphatic ducts. The Nerves are derived from the cardiac plexuses, which are formed partly from the cranial nerves and partly from the sympathetic.

## THE RIGHT HEART.

The Right Auricle is slightly larger than the left, its walls somewhat thinner, being about one line in thickness; its cavity contains about 2 fluid-

ounces. It consists of two parts, a principal cavity, the sinus venosus (1) or atrium, situated posteriorly, and a smaller portion, the appendix auriculæ(2), situated anteriorly. It receives the venous blood by the superior (3) and inferior (4) venæ cavæ and the coronary sinus, and presents interiorly the following points for examination:—

Appendix Auriculæ (n),—a conical pouch projecting from the sinus to the front and left, its margins being dentated.

FIG. 61.

Openings—of the superior and inferior venæ cavæ and the coronary sinus (7), the latter having a valve in two segments.

Foramina Thebesii,—several minute orifices, the mouths of veins from the substance of the heart.

Auriculo-ventricular Opening (9),—communicates with the right ventricle, is oval, about 1½ inch broad, surrounded by a fibrous ring, and is guarded by the tricuspid valve.

Fossa Ovalis (5),—a depression on the inner wall, corresponding to the situation of the foramen ovale in the fœtus.

Annulus Ovalis,—the oval margin of the fossa ovalis.

Musculi Pectinati,—muscular columns on the inner surface of the appendix and the inner wall of the auricle.

Tubercle of Lower,—a very small projection on the right wall, supposed to influence the direction of the blood-current.

Eustachian Valve (6),—at the anterior margin of the inferior vena cava; large in the fœtus, to direct the blood to the foramen ovale.

Coronary Valve (Valve of Thebesius) (8),—a semicircular fold which protects the orifice of the coronary sinus and prevents regurgitation of blood into the sinus.

The Right Ventricle (a) is triangular in form and extends from the right suricle to near the apex of the heart. Its anterior surface is rounded and convex and forms the larger part of the front of the heart. Its under surface is flattened and rests upon the diaphragm. Its cavity (b c) can contain about 3 fluidounces, and presents the following points for examination:—

Tricuspid Valve (e, f),—consists of 3 triangular segments connected by their bases with the auriculo-ventricular orifice, and by their sides with each other, the largest being on the left side.

Semilunar Valves (m),—are 3 in number, and guard the orifice of the pulmonary artery, each about the middle of its free margin has a fibrocartilaginous nodule, the corpus Arantii, which more perfectly closes the orifice.

Opening of the Pulmonary Artery,—at the superior and internal angle of the ventricle, the conus arteriosus. It is circular in form, surrounded by a fibrous ring, and is guarded by the semilunar valves.

Sinuses of Valsalva,—are 3 pouches, one behind each valve, between it and the commencement of the pulmonary artery.

Columnæ Carneæ (g),—muscular columns projecting from the surface of the ventricle, of which 3 or 4, called musculi papillares, give attachment to the chordæ tendinæ.

Chordæ Tendinæ (l),—delicate tendinous cords which connect the margins and lower surfaces of the tricuspid valve with the columnæ.

#### THE LEFT HEART.

The Left Auricle is smaller than the right, but has thicker walls, being about 1½ line. Like the right auricle it consists of a principal cavity (1) or

sinus and an appendix auriculæ (2), which overlaps the root of the pulmonary artery. Internally the auricle presents the following parts:—

Openings (3) of the Pulmonary Veins,—are 4 in number, sometimes 3, as the two left veins (5) frequently end in a common opening. They have no valves.

Left Auriculo-ventricular Opening (6),—is smaller than the right one. Musculi Pectinati,—on the inner surface of the appendix.

Depression,—corresponding to the fossa ovalis in the right auricle.

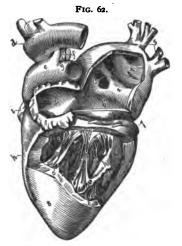

The Left Ventricle (8) is longer, thicker and more conical in shape than the right ventricle (h), and it forms a small part of the anterior surface of the heart but a considerable part of its posterior surface. By its projection

beyond the apex of the right ventricle it forms the apex of the heart. Its walls are the thickest of those in the heart, being thrice as thick as those of the right ventricle. Its interior (9) presents the following:—

Left Auriculo-ventricular Opening,
—is surrounded by a dense fibrous
ring and is guarded by the mitral
valve.

Aortic Opening,—is small and circular, placed in front and to the right of the auriculo-ventricular, a segment of the mitral valve being between them. It is surrounded by a fibrous ring, and guarded by the semilunar valves.

Mitral Valve (a),—consists of two unequal-sized segments, and is attached to the fibrous ring which

surrounds the auriculo-ventricular opening. Its margins are connected with the ventricular walls by chordæ tendinæ and musculi papillares.

Semilunar Valves,—3 in number, guard the aortic orifice, and are larger and stronger than those on the right side.

Sinus of Valsalva,—a pouch in the wall of the aorta opposite each segment of the semilunar valves.

Columna Carnea (b),—are smaller and more numerous than those on the right side; the musculi papillares are but two in number, one connected to the anterior, the other to the posterior wall.

#### THE ARTERIES.

The Arteries are cylindrical tubular vessels which carry blood from the ventricles of the heart to every part of the body. The Aorta and its branches, together with the returning veins, constitute the greater or systemic circulation. The Pulmonary Artery and its branches to the lungs, together with the returning veins, constitute the lesser or pulmonic circulation. The arteries anastomose or communicate freely with each other everywhere throughout the body, permitting the establishment of collateral circulations.

Structure of the Arteries. They are dense in structure, very elastic, preserving their cylindrical form, and are composed of 3 coats, an *Internal* or serous; a *Middle*, composed of muscular and elastic tissue; and an *External*, composed of connective tissue. They are generally included in a fibroareolar investment, the *Sheath*, which also encloses the accompanying veins. The larger arteries are nourished by the *Vasa Vasorum*, blood-vessels which ramify in the external and middle coats; and are supplied with nerves, the *Vaso-motor*, derived from both the sympathetic and cerebro-spinal systems, and forming intricate plexuses on the larger trunks.

The Capillaries are minute vessels forming a network throughout the tissues of the body between the terminating arteries and the commencing veins. Their average diameter is about the  $\frac{1}{3000}$  of an inch, and their walls consist of a transparent homogeneous membrane continuous with the innermost layer of the arterial and venous walls.

[In the following pages, main branches are in italics, sub-branches in Roman.]

# THE PULMONARY ARTERY AND AORTA.

The Pulmonary Artery alone of the arteries carries venous blood, which it conveys from the right side of the heart to the lungs. It is 1½ inch in diameter and only about 2 inches long, and all within the pericardium; arising from the right ventricle in front of the ascending aorta, passing upward and backward to the under surface of the arch of the aorta, where it bifurcates, and is connected at its root to the aorta by a fibrous cord, the remains of the ductus arteriosus of the fœtus. Its terminal branches are the—

Right and Left Pulmonary Arteries,—the latter being the shorter of the two; they pass horizontally outward to the roots of their respective lungs, where each divides into two branches, which again and again subdivide to ramify throughout the lung tissue and end in the capillaries of those organs.

The Aorta is the main trunk of the systemic arteries, commencing at the

aortic opening of the left ventricle of the heart, it arches backward over the roof of the left lung into the thorax, where it descends on the left of the spinal column, and after passing through the aortic opening in the diaphragm, it terminates in the right and left common iliac arteries opposite the 4th lumbar vertebra. It is divided into the Ascending Aorta (5), the Arch (6), and the Descending Aorta (12), the last-named being again divided into the Thoracic Aorta and the Abdominal Aorta (described under Arteries of the Trunk). The upper border of the arch is generally situated about an inch below the upper margin of the sternum. The branches of the aorta are—

From the Ascending Aorta,—2 Coronary Arteries (4).

Bronchial.

From the Arch,—Innominate (7). Left Common Carotid (10).

Left Subclavian (11).

From the Thoracic,—Pericardiac.

Œsophageal. 18 Intercostals.

Posterior Mediastinal.

From the Abdominal,—2 Phrenic.

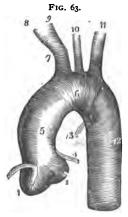

Cæliac Axis. Gastric. 2 Spermatic, in the m. 2 Ovarian, in female. Splenic. Inferior Mesenteric.

Superior Mesenteric.
2 Supra-renal.
2 Renal.

2 Spermatic, in the male.
2 Ovarian, in female.
Inferior Mesenteric.
8 Lumbar.
Sacra Media.
2 Common Iliac.

The Coronary Arteries are 2 in number, a right and a left (4), arise from the aorta in the sinuses of Valsalva behind the semilunar valves, and run in the vertical grooves of the heart, the left artery in front, to supply the tissue of that organ. Each artery divides into 2 branches, the transverse and the descending, the latter anastomosing at the apex of the heart with its fellow of the opposite side. The descending branch of the right coronary sends off a marginal branch along the margin of the right ventricle, and an infundibular branch to the conus arteriosus of the same ventricle.

The Innominate Artery (7) arises from the summit of the arch of the aorta, is  $1\frac{1}{2}$  inch long, and divides behind the right sterno-clavicular joint into the Right Common Carotid (9) and

Right Subclavian (8), these arteries on the left side of the body (10, 11) arising directly from the arch of the aorta. It sometimes sends off a small

branch, the *Thyroidea ima*, to the thyroid body; which vessel may arise from the arch of the aorta, the right common carotid, the subclavian, or the internal mammary. The Innominate artery is sometimes absent and not infrequently varies in length from  $1\frac{1}{2}$  inch to 2 inches.

#### ARTERIES OF THE HEAD AND NECK.

The Common Carotid Arteries. Arising differently (see above) the two carotids are similarly described, except that the left is longer and deeper than the right one. Their course is indicated by a line drawn from a point midway between the angle of the lower jaw and the mastoid process to the sterno-clavicular articulation. At the lower part of the neck they are separated only by the width of the trachea, and they are each contained in a sheath of the deep cervical fascia with the internal jugular vein externally and the pneumogastric nerve between the artery and vein. On the front of the sheath lies the descendens noni nerve (descending branch of the 9th or hypoglossal). The artery lies beneath the inner border of the sterno-cleido-

mastoid muscle, and is crossed about its middle by the omohyoid muscle and the middle thyroid vein. It is also crossed above by the facial, lingual, and superior thyroid veins, below by the anterior jugular vein, and on the left side often by the internal jugular vein. It bifurcates, at the level of the upper border of the thyroid cartilage, into the External and Internal Carotids, of which the internal is the most remote from the median line.

The External Carotid Artery (2) (Fig. 64) commences opposite the upper border of the thyroid cartilage, and passes upward, forward and backward to the space between the neck of the condyle of the lower jaw and the external meatus, where

it divides into the temporal and internal maxillary arteries. It has 8 branches the—

Superior Thyroid (4),—arising below the greater cornu of the hyoid bone.

Muscular. Hyoid. Superior Laryngeal.

Glandular. Superficial Descending. Crico-thyroid.

Lingual (5),—under the hyo-glossus muscle to the tongue; giving off—

Hyoid. Dorsalis Linguæ. Sublingual. Ranine.

Facial (6),—crosses the lower jaw at the anterior angle of the masseter; giving off—

Inferior (Ascending) Palatine. Submental (7). 2 Coronary (8, 9). Tonsillar. Muscular. Lateralis Nasi.

Submaxillary. Inferior Labial. Angular.

Occipital (10),—lies in the occipital groove of the temporal bone.

Muscular. Auricular. Arteria Princeps Cer-Sterno-mastoid. Meningeal. vicis (13).

Posterior Auricular (14),—ascends under cover of the parotid gland.

Stylo-mastoid. Auricular. Mastoid. Muscular. Glandular.

Ascending Pharyngeal, -- lies on the rectus capitis anticus major.

Prevertebral. Pharyngeal. Tympanic. Meningeal.

Superficial Temporal (15),—the smallest of the termini of the external carotid, begins in the parotid gland, crosses the zygomatic arch, and divides into anterior (13) and posterior temporal (16). Its branches are the—

Transverse Facial (15). Middle Temporal (17). Anterior Auricular.

Internal Maxillary (4),—the other terminal branch of the external car-

otid (1), is divided into three portions, Maxillary (4), Pterygoid (5), and Spheno-maxillary (6), which respectively give off the following branches: (Fig. 65.)

Maxillary.

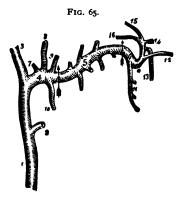

Deep Auricular, to the tragus and canal.

Tympanic (7), entering the Glaserian fissure.

Middle Meningeal (8).

Small Meningeal (9).

Inferior Dental (10), divides into Incisor and Mental.

Pterygoid.

Deep Temporal, ant. and posterior.

Pterygoid Branches, to those muscles.

Masseteric, to the masseter mus-

Buccal, to the buccinator muscle.

Spheno-maxillary.

Alveolar (11). Infra-orbital (12).

Descend. Palatine (13).

Vidian (16).

Pterygo-palatine (15).

Spheno-palatine or Naso-pala-

tine (14).

The Internal Carotid Artery commences at the bifurcation of the common carotid and ascends in front of the transverse processes of the three upper cervical vertebræ, and close to the tonsil, traverses the carotid canal in the temporal bone, and after piercing the dura mater close by the anterior clinoid process, divides into its terminal (cerebral) branches. It curves remarkably in different parts of its course, in the carotid canal and alongside the body of the sphenoid bone it describes a double curvature resembling the italic letter S placed horizontally. In the cervical portion no branches are given off; in the petrous, cavernous and cerebral portions it gives off the following:—

Tympanic,—enters the tympanum from the carotid canal, and anastomoses on the membrana tympani with the tympanic branch of the internal maxillary and the stylo-mastoid.

Arteria Receptaculi,—numerous small vessels going to the walls of the sinuses, the Gasserian ganglion and the pituitary body.

Anterior Meningeal,—a small branch to the dura mater of the anterior fossa, after passing over the lesser wing of the sphenoid.

Ophthalmic,—arises from the cavernous portion, enters the orbit through the optic foramen, terminating at the inner angle of the eye into the frontal and nasal branches. It gives off the following branches:—

Ocular Group. Orbital Group. Art. Centralis Retinæ. Lachrymal. Frontal. Muscular. Supra-orbital. Nasal. Anterior Ciliary. Posterior Ethmoidal. (the Short Ciliary. Anterior Ethmoidal. terminal Long Ciliary. Internal Palpebral. branches).

Anterior Cerebral,—joined to its fellow by the Anterior Communicating Artery, about 2 lines long; then runs alongside its fellow, terminating by anastomosis with the posterior cerebral arteries, and giving off the following branches:—

Antero-median Ganglionic. Inferior Internal Frontal. Ant. Internal Frontal.
Middle Internal Frontal.

Posterior Internal Frontal.

Middle Cerebral,—in the fissure of Sylvius; divides into:—

Antero-lateral Ganglionic.

· Ascending Frontal.

Inferior External Frontal.

Ascending Parietal.

Parieto-temporal.

Posterior Communicating,—anastomoses with the posterior cerebral, a branch of the basilar, and gives off the:—

Postero-median Ganglionic, branches supplying the optic thalami and the walls of the 3rd ventricle.

Anterior Choroid,—to the hippocampus major, corpus fimbriatum, etc., and ends in the choroid plexus.

[The Vertebral Artery, a branch of the Subclavian, and the Basilar Artery, formed by the junction of the two vertebrals, may be considered arteries of the head and neck, but they are most conveniently described as branches of the Subclavian Artery (see below).]

#### THE CIRCLE OF WILLIS.

The Circle of Willis is a remarkable anastomosis at the base of the brain, formed by the branches of the vertebral and internal carotid arteries, and giving origin to the 3 trunks which supply each cerebral hemisphere. Posteriorly, the two Vertebral arteries unite to form the Basilar, which ends in the two Posterior Cerebral. Anteriorly, each Internal Carotid gives off the Anterior Cerebral, these latter being connected by the short Anterior Communicating arteries, one on each side, which connect the posterior cerebral with the internal carotid.

The Circle of Willis gives off,—anteriorly, the anterior cerebral arteries; antero-laterally, the middle cerebral; and posteriorly, the posterior cerebral; each artery giving origin to two very different arterial systems: the Central Ganglionic System, supplying the central ganglia of the brain; the Cortical Arterial System, which ramifies in the pia mater and supplies the cortex and subjacent medullary substance. These two systems, though having a common origin, do not communicate afterwards, and in their distribution are entirely independent of each other. Hence, between the parts supplied by each, there is a zone of diminished nutritive activity, where softening may be especially liable to occur in the brains of old people. By the Circle of Willis the cerebral circulation is equalized and provision made for carrying it on if one or more of the branches should be obliterated.

#### THE TRIANGLES OF THE NECK.

Anterior Triangle of the Neck is bounded, in front, by a line extending from the chin to the sternum; behind, by the anterior margin of the sterno-

mastoid muscle; its base, directed upward, is formed by the lower border of the body of the jaw and a line extending from the angle of the jaw to the mastoid process; its apex is below, at the sternum. It is crossed by the digastric muscle above and the anterior belly of the omo-hyoid below, dividing it into 3 smaller triangles, named from below upward the Inferior Carotid, the Superior Carotid, and the Submaxillary triangles.

Inferior Carotid Triangle, situated below the anterior belly of the omo hyoid, contains at its posterior edge in a common sheath the lower portion of the common carotid artery, the pneumogastric nerve and the internal jugular vein, concealed by the sterno-mastoid muscle, also other structures, which with the former may be summarized as follows:—

Muscles,—the sterno-hyoid and sterno-thyroid, covering the common carotid artery.

Arteries,—the common carotid and the inferior thyroid.

Veins,—the internal jugular, as described above.

Nerves,—the pneumogastric, recurrent laryngeal, and sympathetic, also filaments from the loop between the descendens and communicans hypoglossi.

Other Structures,—the trachea, thyroid gland, and the lower part of the larynx.

Superior Carotid Triangle, situated above the anterior belly of the omohyoid, contains the upper part of the common carotid artery and its bifurcation into the internal and external carotid, also other structures, all summarized as follows:—

Muscles,—parts of the thyro-hyoid, hyo-glossus, inferior and middle constrictors of the pharynx.

Vessels,—the common carotid artery, the internal and external carotid arteries, and the internal jugular vein; the superior thyroid, lingual, facial, occipital and ascending pharyngeal branches of the external carotid and the veins accompanying them.

Nerves,—the pneumogastric, spinal accessory, hypoglossal, descendens hypoglossi, sympathetic, internal and external laryngeal.

Other Structures,—the upper part of the larynx, and the lower part of the pharynx.

Sub-maxillary Triangle, immediately below the body of the jaw, and above the posterior belly of the digastric and the stylo-hyoid; contains the following:—

Muscles,—the mylo-hyoid, hyo-glossus, stylo-glossus, and stylo-pharyngeus.

Arteries,-the external and internal carotid; also the facial, posterior

auricular, temporal, internal maxillary, submental, and mylo-hyoid arteries.

Veins,—the facial and internal jugular.

Nerves,—the pneumogastric, glosso-pharyngeal, facial, and mylo-hyoid. Glands,—the parotid and sub-maxillary.

Posterior Triangle of the Neck is bounded, in front by the sternomastoid muscle; behind, by the trapezius; its base corresponds to the middle Lard of the clavicle, its apex is at the occiput. It is crossed by the posterior belly of the omo-hyoid muscle about an inch above the clavicle, subdividing it into two smaller triangles, the Occipital above, and the Subclavian below.

Occipital Triangle, the larger division of the posterior triangle of the neck, above the posterior belly of the omo-hyoid muscle, contains the following:—

Muscles,—the splenius, levator anguli scapulæ, middle and posterior scaleni.

Vessels,—the transversalis colli artery and vein.

Nerves,—the spinal accessory, and descending branches of the cervical plexus.

Glands,—a chain of lymphatic glands.

Subclavian Triangle, the smaller of the divisions of the posterior triangle of the neck, situated below the posterior belly of the omo-hyoid muscle, and above the middle third of the clavicle, contains the following:—

Vessels,—the subclavian artery, the subclavian vein occasionally, the transversalis colli and suprascapular arteries and veins, the external jugular and transverse cervical veins.

Nerves,—the brachial plexus, descending branches of the cervical plexus, nerve to the subclavius muscle.

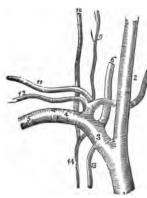

Glands,—a lymphatic gland.

#### ARTERIES OF THE UPPER EXTREMITY.

The Subclavian Artery arises on the right side from the innominate, on the left side from the arch of the aorta, and is divided into 3 portions by the scalenus anticus muscle, which crosses it just external to the origin of the thyroid axis, viz.—the parts internal, behind, and external to that muscle. At the outer border of the 1st rib, the subclavian becomes the Axillary Artery. Its upper border is a little above the clavicle, and it is separated from the subclavian vein by the scalenus anticus at its origin from the first rib. Its branches are all given off from its first portion, except the Superior Intercostal, which on the right side arises from the second portion. Its branches are the—

VERTEBRAL (6),—passing up the neck, through the foramina in the trans-

verse processes of six cervical vertebræ, enters the skull by the foramen magnum, where it joins its fellow to form the Basilar Artery. Its branches are-

> Lateral Spinal Branches. Muscular Branches. Posterior Meningeal. Anterior Spinal. Posterior Spinal. Posterior Inferior Cerebellar. Buibar.

The Basilar,—formed by the junction of the vertebrals, gives off on each side a transverse, anterior, and superior cerebellar, and ends in the two posterior cerebral. (See Circle of Willis, page 123.)

THYROID Axis (8),—at once divides into the three following branches: Inferior Thyroid (7),—to the thyroid gland, giving off—

Inferior Laryngeal.

Esophageal Branches.

Tracheal. Muscular.

Ascending Cervical (9).

Suprascapular (12),—to the shoulder-joint and the dorsum of the scapula, anastomosing there with the posterior- and sub-scapular.

Transversalis Colli (11).—divides beneath the margin of the trapezius into

Superficial Cervical.

Mediastinal.

Posterior Scapular.

INTERNAL MAMMARY (13),—arises opposite the thyroid axis, descends upon the costal cartilages, and ends at the 6th interval, in the musculophrenic and superior epigastric, the latter anastomosing with the deep epigastric branch of the external iliac. Its branches are the-

Pericardiac. Comes Nervi Phrenici.

Perforating.

or Superior Phrenic. Sternal. Anterior Intercostal.

Musculo-phrenic. Superior Epigastric.

SUPERIOR INTERCOSTAL (14),—gives off branches in the intercostal spaces to the posterior spinal muscles and to the spinal cord. One branch, the-

Profunda Cervicis (10),-supplies the muscles of the back of the neck, and anastomoses with the arteria princeps cervicis of the occipital. This vessel occasionally arises from the subclavian artery.

The Axillary Artery (5), the continuation of the subclavian, commences at the outer border of the first rib, and terminates at the lower border of the tendon of the teres major muscle, where it becomes the brachial artery. The pectoralis minor crosses it and marks its division into three portions,—
1st, above; 2nd behind, and 3rd below that muscle. The brachial plexus is in close relation with the artery, surrounding it on three sides in the second portion. Its branches are 7 in number, as follows:—

Superior Thoracic,—from the first portion; supplies the pectoral muscles and the walls of the thorax.

Acromial Thoracic,-from the first portion; divides into the-

Thoracic Branches 2 or 3,—to the serratus magnus and pectorals.

Acromial Branches,-to the deltoid muscle.

Descending or Humeral,—to the pectoralis major and deltoid.

Clavicular,—a very small branch, to the subclavius muscle.

Alar Thoracic,—from the second portion; to the glands and the areolar tissue of the axilla.

Long Thoracic,—from the second portion; to the serratus magnus, the pectoral muscles and the mammary gland.

Subscapular,—from the third portion; to the inferior angle of the scapula, where it anastomoses with the long thoracic, the intercostal and the posterior scapular arteries. It gives off small branches to the deltoid and triceps muscles, and the

Dorsalis Scapulæ,—a large branch, to the subscapular fossa and the axillary border of the scapula.

Posterior Circumflex,—from the third portion; winds around the neck of the humerus to the deltoid muscle and the shoulder-joint, anastomosing with the anterior circumflex and other arteries.

Anterior Circumflex,—from the third portion; winds around the neck of the humerus, to the head of that bone, the deltoid muscle and the shoulder-joint, anastomosing with the posterior circumflex.

The Brachial Artery is the continuation of the axillary from the lower margin of the teres major tendon to its bifurcation into the radial and ulnar, which is usually about half an inch below the bend of the elbow. The median nerve crosses it from the outside to the inside about its middle. Above its bifurcation it is crossed diagonally by the bicipital fascia. The basilic vein lies on its inner side but separated from it in the lower part of the arm by the deep fascia. Its branches are the—

Superior Projunda,—winds over the arm in the spiral groove, giving off the posterior articular to the elbow anastomosis, and a branch to anastomose with the recurrent branch of the radial, and a nutrient artery to the bone. This artery supplies the triceps muscle.

Nutrient Branch,—enters the nutrient canal of the humerus.

Injerior Projunda,—to the elbow-joint anastomosis.

Anastomotica Magna,—anastomoses with the posterior articular, inferior profunda, anterior and posterior ulnar recurrent.

Muscular Branches,—to the muscles in the course of the artery.

The Radial Artery extends from the bifurcation of the brachial to the deep palmar arch, and gives off the following branches:—

In the Forearm,-

Radial Recurrent,—to the supinators, the brachialis anticus and the elbow joint, anastomosing with the terminal branches of the superior profunda-Muscular Branches,—to the muscles on the radial side of the forearm.

Anterior Carpal,—anastomoses with the anterior carpal of the ulnar artery, forming the Anterior Carpal Arch.

Superficialis Vola,—to the muscles of the thumb.

In the Wrist,-

Posterior Carpal,—anastomoses with the posterior carpal of the ulnar artery forming the Posterior Carpal Arch.

Metacar pal,—the first dorsal interosseous branch, divides into two dorsal digital branches, supplying the adjoining sides of the index and middle fingers.

Dorsales Pollicis 2,—along the sides of the thumb.

Dorsalis Indicis, -- along the radial side of the index finger.

In the Hand,-

Princeps Pollicis,—along the sides of the palmar aspect of the thumb by two branches forming an arch.

Radialis Indicis,—along the radial side of the index finger to anastomose with the collateral digital and the princeps pollicis, giving a communicating branch to the superficial palmar arch.

Perforating 3,—backward from the deep palmar arch to anastomose with the dorsal interosseous arteries.

Palmar Interoseous 3 or 4,--from the deep palmar arch, on the interossei muscles to anastomose with the digital branches of the superficial arch.

Palmar Recurrent,—from the deep palmar arch to the carpal joints, anastomosing with the anterior carpal arch.

The Ulnar Artery extends from the bifurcation of the brachial just below the bend of the elbow along the ulnar border of the forearm to the wrist. Immediately beyond the pisiform bone it divides into two branches which

enter into the formation of the superficial and deep palmar arches. Its branches are as follows:—

in the Forearm.-

Anterior Ulnar Recurrent,—anastomoses in front of the inner condyle of the humerus with the anastomotica magna and the inferior profunda.

Posterior Ulnar Recurrent,—anastomoses behind the inner condyle of the humerus with the anastomotica magna, inferior profunda and inter-osseous recurrent.

Interosseous,—about ½ inch long, divides into two branches. The Anterior Interosseous gives off the Median Artery to the median nerve and a Nutrient branch to both bones of the forearm. The Posterior gives off near its origin the Interosseous Recurrent to the elbow-joint anastomosis. Muscular,—to the muscles on the ulnar side of the forearm.

In the Wrist,-

Anterior Carpal,—anastomoses with a corresponding branch of the radial artery in front of the carpus.

Posterior Carpal,—anastomoses with a corresponding branch of the radial artery forming the posterior carpal arch.

In the Hand,-

Deep or Communicating,—anastomoses with the termination of the radial artery, completing the deep palmar arch.

Superficial Palmar Arch,—is the continuation of the trunk of the ulnar artery in the hand.

Digital 4,—given off by the superficial palmar arch.

#### THE CARPAL ARCHES.

The Anterior Carpal Arch is formed by the anastomosis of the anterior carpal of the radial with the anterior carpal of the ulnar artery in front of the wrist. It is joined by branches from the anterior interosseous above and by recurrent branches from the deep palmar arch below, and gives off branches to supply the articulations of the wrist and carpus.

The Posterior Carpal Arch is formed by the anastomosis of the posterior carpal of the radial with the posterior carpal of the ulnar artery. It is joined by the termination of the anterior interosseous artery and gives off dorsal interosseous arteries for the third and fourth interosseous spaces, which divide into dorsal digital branches which supply the adjacent sides of the middle ring and little fingers, and communicate with the digital arteries of the superficial palmar arch, and at their origin with the perforating branches from the deep palmar arch.

#### THE PALMAR ARCHES.

The Superficial Palmar Arch is formed by the part of the ulnar artery which lies in the palm of the hand, and is completed by that artery anastomosing with a branch from the radialis indicis, at the root of the thumb; sometimes with the superficialis volæ or the princeps pollicis of the radial. It gives off 4 Digital branches to the sides of the fingers, except the radial side of the index finger, which with the thumb is supplied from the radial artery.

The Deep Palmar Arch is formed by the palmar portion of the radial artery, and is completed by the anastomosis of that artery with the deep palmar (communicating) branch of the ulnar. It lies upon the carpal ends of the metacarpal bones and the interossei muscles, about ½ inch nearer to the carpus than the superficial palmar arch, from which it is separated by the annular ligament, the flexor brevis minimi digiti, the superficial flexor tendons and divisions of the median and ulnar nerves. From it are given off the radialis indicis, palmar interosseous, perforating and palmar recurrent branches of the radial artery.

## ARTERIES OF THE TRUNK.

#### THE DESCENDING AORTA.

The Descending Aorta is divided into two portions, the *Thoracic Aorta* and the *Abdominal Aorta*, corresponding to the two great cavities of the trunk in which they are situated.

The Thoracic Aorta commences at the lower border of the 4th dorsal vertebra on the left of the spine, and descends in the back part of the posterior mediastinum, terminating at the aortic opening in the diaphragm directly in front of the lower border of the last dorsal vertebra. Its branches are—

Pericardiac,—irregular in origin, to the pericardium.

Bronchial,—vary in number and origin; generally one on the right side and two on the left. They nourish the lungs, bronchial glands and the cesophagus.

Œsophageal, 4 or 5,—anastomose on the cesophagus with branches of the inferior thyroid, phrenic, and gastric arteries.

Posterior Mediastinal,—numerous small vessels supplying the glands and the areolar tissue in the mediastinum.

Intercostals,—usually 9 on each side, the two superior intercostal spaces being supplied by the superior intercostal branch of the subclavian. They run between the two layers of intercostal muscles, anastomose

with the anterior intercostal branches of the internal mammary, and each gives off the following branches:—

Posterior or Dorsal,—to the muscles and skin of the back.

Spinal,—to the spinal cord and its membranes.

Collateral Intercostal,—along the upper border of the rib below.

The Abdominal Aorta begins where the thoracic aorta ends (see above),

and terminates on the body of the 4th lumbar vertebra, where it divides into the two common iliac arteries. Its branches are as follows:—

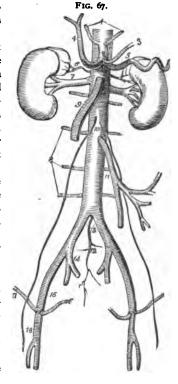

Phrenic (1),—one on each side, but usually only one arises from the aorta, the other springing from either the coeliac axis or the renal artery. They go to the under surface of the diaphragm, where each artery divides into two branches, an external and an internal, the former to the side the latter to the front of the thorax and the diaphragm.

CŒLIAC AXIS (2), arises from the aorta, close to the margin of the opening in the diaphragm, runs forward for half an inch, and divides into the Gastric, Hepatic, and Splenic arteries, occasionally giving off one of the phrenics.

The—

Gastric (3),—supplies the stomach along its lesser curvature, anastomosing with the aortic cesophageal, splenic, and hepatic branches.

Hepatic (4),—forms the lower boundary of the foramen of Winslow, passes upward to the transverse fissure of the liver where it divides

into two branches, right and left, supplying the corresponding lobes of that organ. Its branches are the—

Pyloric,—to the pyloric end of the stomach and along the lesser curvature of that viscus.

Gastro-duodenalis,—giving off the Gastro-epiploica Dextra along the greater curvature of the stomach, and the Pancreatico-duodenalis Superior to the contiguous margins of the duodenum and pancreas.

Right Hepatic,—to the right lobe of the liver, giving off the Cystic Artery to the gall-bladder.

Left Hepatic,—to the left lobe of the liver.

Splenic (5),—the largest branch of the coeliac axis, passes by a very tortuous course to the spleen, giving off the following:—

Pancreaticæ Parvæ. Gastric (vasa brevia), to the stomach.

Pancreatica Magna. Gastro-epiploica Sinistra, to the stomach.

Terminal Branches, enter the hilum of the spleen.

Superior Mesenteric (9),—supplies the small intestine, cæcum, ascending and transverse colon. Arising about one-fourth inch below the cœliac axis it arches forward, downward, and to the left, giving off the—

Inferior Pancreatico-duodenal. Ileo-colic.

Vasa Intestini Tenuis, 12 to 15. Colica Dextra and Media.

Supra-renal (6),—arise one on each side, opposite the origin of the superior mesenteric, passing to the supra-renal capsules.

Renal (7),—one from each side, just below the preceding, pass to the kidney, at its hilum having the middle place between the ureter behind and the renal vein in front. U. A. V. (you 'ave!)

Spermatic (10),—one on each side, in the male through the inguinal canal to the testes; in the female it is called Ovarian, going to the ovaries, uterus and skin of the labia and groins.

Inferior Mesenteric (11),—supplies the descending colon, sigmoid flexure, and most of the rectum, giving off the following branches:—

Colica Sinistra. Sigmoid. Superior Hemorrhoidal.

Lumbar (8),—usually 4 on each side, analogous to the intercostals. They each divide into two branches, the—

Dorsal, giving off a spinal branch. Abdominal.

Middle Sacral (12),—arises just at the bifurcation of the aorta; it descends along the last lumbar vertebra and the front of the sacrum to the upper part of the coccyx, giving off numerous branches on each side to anastomose with the lateral sacral arteries. It terminates in a minute branch which goes to the coccygeal gland (Luschka), and sends off branches to the rectum.

# THE ILIAC ARTERIES.

The Common Iliac Arteries extend from the bifurcation of the aorta at the 4th lumbar vertebra to the lumbo-sacral articulation, where each divides

into the External Iliac (15) and the Internal Iliac (14); the former supplying the lower extremity, the latter going to the viscera and walls of the pelvis. The common iliac arteries are about 2 inches in length, the right being a little longer than the left, and each is crossed by the ureter, just before its bifurcation.

The Internal Iliac (14) is about 1½ inches long, extending from the lumbosacral articulation to the great sacro-sciatic notch, where it divides into an interior and a posterior trunk. From the Anterior Trunk are given off, from above downward, the—

Superior Vesical,—the remaining pervious part of the fœtal hypogastric artery. It sends branches to the bladder, the vas deferens and the ureter; and one, the Middle Vesical, to the base of the bladder.

Obturator,—through the canal in the obturator membrane to the thigh, where it divides into an internal and external branch. Within the pelvis it gives off an iliac, a vesical, and a pubic branch. In one out of every 3½ cases this artery arises from the epigastric, in 2 out of every 3 from the internal iliac, in 1 out of 72 by two roots from both vessels and in about the same proportion from the external iliac.

Inferior Vesical,—to the bladder, prostate gland, and vesiculæ seminales. In the female this artery is called the Vaginal.

Middle Hemorrhoidal,—to the anus and parts outside the rectum.

Uterine,—in the female, anastomosing with a branch from the ovarian. It gives off cervical branches to the cervix uteri and the azygos arteries of the vagina.

Internal Pudic,—the smaller of the terminal branches of the anterior trunk, supplies the external generative organs. Its muscular branches in the pelvis are numerous and small; in the perineum they are the—

Inferior Hemorrhoidal. Artery of the Bulb.

Superficial Perineal. Artery of the Corpus Cavernosum.

Transverse Perineal. Dorsal Artery of the Penis.

Sciatic,—the other terminal branch, supplies the muscles on the back of the pelvis. Its branches are the—

Muscular (internal).Coccygeal.Muscular (ext.).Hemorrhoidal Brs.Inferior Gluteal.Anastomotic.Vesical Branches.Comes Nervi Ischiadici.Articular.

THE POSTERIOR TRUNK gives off the following:-

Ilio-lumbar,—dividing into a lumbar and an iliac branch.

Lateral Sacral,—superior and inferior on each side.

Gluteal,—the continuation of the posterior trunk, divides into a superficial and a deep branch, to the glutei muscles, the skin over the sacrum, and

the hip-joint. Before dividing it gives a nutrient branch to the ilium, and some muscular branches.

The External Iliac extends to beneath the centre of Poupart's ligament, where it enters the thigh and becomes the Femoral Artery; lying between the femoral vein on the inside and the anterior crural nerve on the outside—V.A.N. Its branches are small muscular and glandular, and the—

Deep Epigastric,—which arises a few lines above Poupart's ligament, passes between the peritoneum and the transversalis fascia, to the sheath of the rectus which it perforates, and ascends behind that muscle, to anastomose by numerous branches with the terminal branches of the internal mammary and inferior intercostal. It gives off the—

Cremasteric. Pubic. Muscular Branches.

Deep Circumflex Iliac,—arises opposite to the epigastric, passes along the crest of the ilium to about its middle, where it pierces the transversalis and runs backward between that muscle and the internal oblique to anastomose with the ilio-lumbar, gluteal, lumbar and epigastric arteries.

#### ARTERIES OF THE LOWER EXTREMITY.

The Femoral Artery extends from Poupart's ligament to the opening in the adductor magnus, where it becomes the *popliteal artery*. Its course corresponds to a line drawn from a point midway between the anterior superior spine of the ilium and the symphysis pubis, to the inner side of the inner condyle of the femur. It lies in a strong fibrous sheath with the femoral vein, but divided from the latter by a fibrous partition. It may be divided into two portions, the Common Femoral and the Superficial Femoral, for convenient description, as follows:—

The Common Femoral Artery,—about 2 inches long, is very superficial, rests on the inner margin of the psoas muscle, which separates it from the capsular ligament of the hip-joint, and is covered by the skin, superficial fascia, superficial inguinal glands, iliac portion of the fascia lata, and the anterior part of the sheath of the vessels.

The Superficial Femoral Artery,—is only superficial in Scarpa's triangle, being deeper in Hunter's canal. It lies above on the femoral vein and the profunda artery and vein; below, on the adductor longus and adductor magnus muscles. The internal saphenous nerve crosses it from without inward.

Branches of the Femoral Artery, are as follows:-

Superficial Epigastric (c),—through the saphenous opening to ascend on the abdomen, giving off branches to the skin, the superficial fascia and the superficial inguinal glands.

Superficial Circumflex Iliac (j),—to the crest of the ilium, supplying the skin of the groin, the superficial fascia,

and the superficial inguinal glands.

Superficial External Pudic (d),—through the saphenous opening to the skin of the abdomen, the penis and the scrotum, (and the labium in the female).

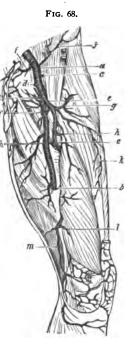

Deep External Pudic (d),—to the skin of the scrotum and perinæum, (and the labium in the female).

Profunda Femoris (Deep Femoral Artery) (e),—arises posteriorly about 1 or 2 inches below Poupart's ligament, and descends to the lower third of the back of the thigh, giving off the following branches:—

Ext. Circumflex (g). Int. Circumflex (f). 3 Perforating (h).

Muscular Branches (k),—to the sartorius and vastus internus.

Anastomotica Magna,—arises from the femoral in Hunter's canal and divides into a superficial and a deep branch, the latter anastomosing around the knee-joint with the superior external and internal articular arteries, and the recurrent branch of the anterior tibial.

Scarpa's Triangle is a triangular space in the thigh which corresponds to the depression seen immediately below the fold of the groin. Its apex is downward, its base formed by Poupart's ligament, and its sides externally by the sartorius, internally by the adductor longus. Its floor is formed by the iliacus, psoas, pectineus and adductor longus muscles, from without inward. It is bisected vertically by the femoral vessels, which extend from the middle of its base to its apex. It also contains the anterior crural nerve external to the vessels, together with lymphatic vessels and glands and some fat.

Hunter's Canal is an aponeurotic space in the middle third of the thigh, extending from the apex of Scarpa's triangle to the femoral opening in the adductor magnus muscle, and lying beneath the sartorius. It contains the

femoral vessels in their sheath, the vein lying behind and to the outer side of the artery; also the long saphenous nerve, at first external to and then in front of the vessels.

The Popliteal Artery, the continuation of the femoral, extends from the opening in the adductor magnus, passing behind the knee-joint, to the lower border of the popliteus muscle, where it divides into the Anterior and Posterior Tibial Arteries. It is crossed by the popliteal vein and the internal popliteal nerve, and gives off the following-named branches, which are distributed around the knee-joint in a free anastomosis; except the Azygos Articular, which pierces the posterior ligament of the joint to reach the internal ligaments and the synovial membrane. Branches are named as follows:—

Superior Muscular Branches. Superior Articular (internal and external).

Inferior Muscular, or Sural. Azygos Articular.

Cutaneous Branches. Inferior Articular (internal and external).

The Anterior Tibial Artery extends from the bifurcation of the popliteal to the front of the ankle-joint, where it becomes the *Dorsalis Pedis*. It passes between the two heads of the tibialis posticus, over the upper edge of the interosseous membrane and along its anterior surface, resting on the tibia for its lower third. It is accompanied by the anterior tibial nerve close to it externally, and is crossed below by the tendon of the extensor proprius hallucis. Its branches are named the—

Posterior Recurrent Tibial. Muscular.

Superior Fibular. Internal Malleolar.

Anterior Recurrent Tibial. External Malleolar.

The Dorsalis Pedis Artery, the continuation of the anterior tibial, extends from the front of the ankle-joint along the tibial side of the foot, to the back part of the 1st intermetatarsal space, where it terminates in the Dorsalis Hallucis and the Communicating. The anterior tibial nerve lies close to its outer side. Its branches are as follows:—

Tarsal,—passing outward along the tarsus.

Metatarsal,—giving off 3 Interosseæ, and they 7 Digital branches.

Dorsalis Hallucis,—to the great toe and the inner side of the second toe by its 3 digital branches.

Communicating,—dips down into the sole of the foot in the 1st interosseous space of the metatarsus, to inosculate with the external plantar, completing the plantar arch. Its plantar digital branch, the arteria magna hallucis, supplies the inner side of the great toe and the adjacent sides of the great and second toes, on their plantar surfaces.

The Posterior Tibial Artery is a large vessel, extending from the bifurcation of the popliteal along the back of the tibia to the fossa below the inner malleolus, where it divides into the *Internal* and *External Plantar*. The posterior tibial nerve crosses it a short way below its origin and then lies near its outer side for the rest of its course. Its branches are as follows:—

Peroneal,—along the fibular side, giving off the following:—

Muscular. Communicating.
Nutrient of the fibula. Posterior Peroneal.
Anterior Peroneal. External Calcanean.

Nutrient of the Tibia,—the largest nutrient artery of bone in the body.

Muscular Branches,—to the posterior muscles of the leg.

Communicating,—to join a similar branch of the peroneal artery.

Internal Calcanean Branches,—to the heel and sole of the foot.

The Internal Plantar Artery, the smallest of the terminal branches of the posterior tibial, passes along the inner side of the foot and great toe.

The External Plantar Artery sweeps across the plantar aspect of the foot in a curve, the convexity of which is directed outward and forward; and at the interval between the bases of the 1st and 2d metatarsal bones it inosculates with the communicating branch from the dorsalis pedis, completing the Plantar Arch, or the Stirrup Anastomosis. It gives off numerous muscular branches, and the—

Posterior Perforating,—3 small branches which ascend through the 3 outer interosseous spaces between the heads of the dorsal interossei muscles. Digital Branches 4,—supplying the sides of the 3 outer toes and the outer side of the 2d toe; its inner side, together with the great toe, being supplied by the communicating branch of the dorsalis pedis.

#### ARTERIAL ANASTOMOSES.

The Anastomosis around the Shoulder-joint is formed by the following 3 arteries, viz.—

Posterior Scapular, br. of transv. colli. Subscapular, br. of axillary. Dorsalis Scapulæ, br. of subscapular. Infraspinous, br. of dorsalis scapulæ. Suprascapular, br. of thyroid axis. Ant. Circumflex, br. of axillary. Post. Circumflex, br. of axillary. Acromial, br. of acromial thoracic.

The Anastomosis around the Elbow-joint is formed by the—
Superior Profunda, br. of brachial.

Posterior Articular, br. of superior profunda.

Radial Recurrent, br. of radial.

Interosseous Recurrent, br. of posterior interosseous.

Inferior Projunda, br. of brachial. Anterior Ulnar Recurrent, br. of ulnar. Anastomotica Magna, br. of brachial. Posterior Ulnar Recurrent, br. of ulnar.

The Anastomotica Magna is the vessel most engaged in this anastomosis, the only part in which it is not employed being that in front of the external condyle of the humerus.

The Anastomosis around the Hip-joint is formed by the—Gluteal, Ilio-lumbar, and Circumflex Iliac, with the External Circumflex. Obturator and Sciatic, with the Internal Circumflex.

Comes Nervi Ischiadici, with the Perforating branches of the Profunda.

The Arteries Anastomosing around the Knee-joint are the-

Descending, br. of ext. circumflex.

Anastomotica Magna, br. of femoral.

Injerior Perjorating, br. of profunda.

Superior Ext. Articular, br. of popliteal.

Ant. Recurrent, br. of anterior tibial.

This anastomosis is sometimes called the deep plexus of the Circumpatellar Anastomosis; a superficial arterial plexus being situated between the fascia and skin around the patella.

The Crucial Anastomosis is formed behind the junction of the neck of the femur with the great trochanter, between the adductor magnus and quadratus femoris muscles, by the anastomosis of the following-named arteries:—

Transverse branch of Ext. Circumflex (from profunda), externally.

Terminal branch of Int. Circumflex (from profunda), internally.

First Perforating branch of the Profunda Femoris, below.

Anastomotic branch of the Sciatic (from int. iliac), above.

The Longest Anastomosis in the Body is that between the subclavian and the external iliac by the anastomosis of the Superior Epigastric, br. of the internal mammary, with the Deep Epigastric, br. of the external iliac.

[The circle of Willis has been described on page 123; the palmar and plantar arches on pages 130 and 137 respectively; and the anastomosis on the membrana tympani on page 122.]

The Collateral Circulation, after Ligature of the Common Carotid Artery, is established by the free communication existing between the carotid arteries of opposite sides both within and without the cranium, and by enlargement of the branches of the subclavian artery on the ligated side. Outside the skull the principal communication takes place by the following anastomoses:—

Superior Thyroid, br. of the external carotid, with the Inferior Thyroid, br. of the thyroid axis (from the subclavian).

Arteria Princeps Cervicis, br. of the occipital (from the external carotid),

with the Vertebral, br. of the subclavian, and the Profunda Cervicis, br. of the superior intercostal, (from the subclavian).

After Ligature of the Subclavian in its first part, the Collateral Circulation is carried on by the following anastomoses:—1, that between the Superior and Inferior Thyroid arteries (see above); 2, that between the two Vertebrals; 3, that between the Internal Mammary, the Deep Epigastric and the Aortic Intercostals; 4, the Superior Intercostal with the Aortic Intercostals; 5, the Profunda Cervicis with the Princeps Cervicis; 6, the Scapular branches of the thyroid axis with branches of the Axillary; 7, the Thoracic branches of the Axillary with the Aortic Intercostals.

## TABLES AND PLATES

OF THE

# ARTERIAL SYSTEM.

NOTE.—The arteries in the following plates should be colored red, by painting them over with ordinary crimson ink, or water-color paint, using a fine camel's-hair brush for the purpose.

#### THE ARTERIAL SYSTEM.

Pulmonary Artery.

(Plate 1.)

R. PULMONARY ART. (Plate 3)
L. PULMONARY ART. (Plate 3)
Carrying Venous blood.

<sup>•</sup> Figures in parentheses in these tables refer to the number of another table, thus— Ext. Carotid (3) means Table No. 3 of the External Carotid Artery.

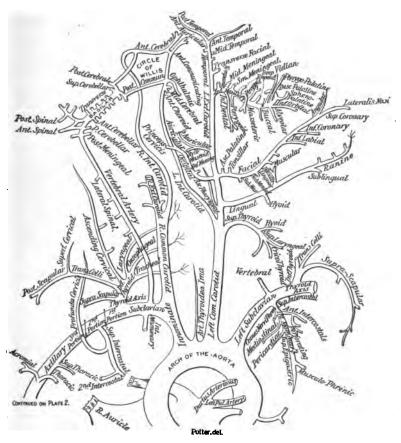

2. Arch of Aorta. (Plate 1.)	R. CORONARY L. CORONARY to the muscular tissue of the heart.		
	INNOMINATE	R. Common Carotid	
		R. SUBCLAVIAN becomes Axillary (8)	Vertebral (5). Thyroid Axis (6). Int. Mammary (7). Sup. Intercostal.
	L. COMMON CAROTID, Same as R. Common Carotid. L. SUBCLAVIAN, Same as R., continuing as Axillary (8).		

Muscular and Glandular branches. Hyoid, along lower border of os hyoides. Superior Superf. Descending, crosses Com. Carotid. Thyroid. Sup. Laryngeal, to larynx and epiglottis. Crico-thyroid, crosses Crico-thyroid membr. Hyoid, along upper border of bone. Dorsalis Linguæ, to tongue, tonsil, palate, etc. Sublingual, to gland, mouth, gums. Ranine, under surface of tongue, to tip. Inf. (Asc.) Palatine, to soft palate and tonsil. Tonsillar, to tonsil and root of tongue. Submaxillary, to gland, skin, muscles. Submental Superf. Br. anas. inf. labial. Deep Br. to the lip. External Carotid. (Plate 1.) Muscular, to pterygoid, masseter, buccinator. Inf. Labial, anas. with br. of 7th and 5th N. Inf. Coronary, anas. with br. of inf. dental art. Sup. Coronary, Art. of Septum Nasi.
Br. to ala of nose. Lateralis Nasi, to ala and dorsum of nose. Angular, termination of facial trunk. Muscular, to digastric, stylo-hyoid, etc. Sterno-mastoid, to that muscle. Auricular, to back part of concha. Inf. Meningeal, to dura mater in post. fossa. Occipital. . Superf. Br. anas. superf. cervical, of trans. colli. Deep Br. anas. vertebral, and deep cerv. br. of

sup. intercostal.

# ARTERIES OF THE HEAD AND NECK.

# Plate 1.

External

### THE ARTERIAL SYSTEM.—Continued.

	Post. Auricular.	Branches (small), to muscles and glands.  Stylo-mastoid, to tympanum, mastoid cells, etc.  Auricular, to cartilage of ear.  Mastoid, to scalp above ear.
3. External Carotid. (Continued.)	Ascending Pharvngeal.	Prevertebral, brs. to muscles and nerves. Tympanic, to inner wall of tympanum. Meningeal Branches, to dura mater. Pharyngeal Branches, 3 or 4 in number.
	Superficial Temporal.	Transverse Facial, lies on the masseter. Anterior Auricular Branches, to pinna, etc. Middle Temporal, supplies that muscle. Auterior Temporal, to the forehead. Posterior Temporal, along side of head.
	INTERNAL MAXILLARY. Divisions: 1. Maxillary. 2. Pterygoid. 3. Spheno- maxillary. 2.	Tympanic { to memb. tympani, anas. with Stylomastoid and Vidian arteries.  Deep Auricular, to outer surface of the membrana tympani.  Mid. Meningeal, to dura and cranial bones.  Small Meningeal, to dura and Gasserian gang.  Lingual, to m.m. of mouth.  Mylo-hyoid, in that groove.  Incisor, { Mental,} Terminal Brs.  Deep Temporal, 2, under temporal muscle.  Pterygoid Brs., to pterygoid muscles.  Masseteric, to deep surface of masseter.  Buccal, a small br. to buccinator.
	3.	Alveolar { Dental, to molars, bicuspids. Branches, to antrum, gums, etc. several brs. to the orbit. Infraorbital { Ant. Dental, to front teeth, antrum. Post. (Desc.) Palatine, to palate, glands, etc. Vidian, to Eustachian tube and pharynx. Pierygo-palatine, to Eustach.tube and pharynx. Spheno-Palatine { Artery of Septum, to septum. External Branches 3, te the nares, antrum, ethmoid and sphenoid cells.

Tympanic, to tympanum by foramen in carotid canal. Arteria Receptaculi (several), in cavernous sinus. Ant. Meningeal, to dura mater of ant. fossa.

OPHTHALMIC. Groups: 1. Orbital. 2. Ocular. (Plate 4. Carotid. Fig. 2.)

Internal

(Plate 1.)

Post. Ethmoidal Meningeal, to dura.
Nasal Brs., to nose. Ant. Ethmoidal, has same branches. Sup. Palpebral, arch on margin of lid. Inf. Palpebral, margin of lower lid. Frontal, to muscles, skin ) Terminal Nasal { Transverse, Dorsalis Nasi. Branches. ( Art. Centralis Retinæ, to the retina.

Lachrymal, to that gland, lid, etc. Supraorbital, the largest sub-branch.

(Ant. Ciliary, to the iris. Muscular \ Superior, to ocular muscles. Inferior, to ocular muscles. Short Ciliary, 6 to 12, around optic n. Long Ciliary 2, to circles on iris.

( Ant. Communicating, 2 lines long. Ganglionic and Frontal branches.

Ganglionic, Frontal, Parietal, and Parieto-temporal branches.

Posterior Communicating, anas. with Post. Cerebral of Basilar, to Anterior Choroid, to the choroid plexus, etc.

#### THE CIRCLE OF WILLIS.

Lateral Spinal {Br. to spinal cord and membranes.
Br. to bodies of Vertebræ posteriorly.

Muscular Branches, to deep cervical muscles.

Post. Meningeal, ramify between dura mater and skull.

Anterior Spinal, { Joins its fellow to form Ant. Median Artery of the spinal cord.

Posterior Spinal, to spinal cord and membranes, laterally.

Post. Inf. Cerebellar { Internal } to cerebellum, and choroid plexus of the 4th Ventricle.

Bulbar, minute branches to the medulla oblongata.

Transverse { to Pons Varolii, etc.
Int. Auditory, to that canal.

Ant. Inf. Cerebellar, { to the cerebellum, anas. with post. inf. cerebellar of Vertebral.

Superior Cerebellar, to pia mater, pineal gland, etc.

Post. Choroid, to choroid plexus.

Ganglionic, to post. lobes.

Ant. Temporal, Post. P

6. Thyroid Axis. (Plate 1.)

VERTEBRAL.

(Plate 1.)

Inferior Thyroid.

Inf. Laryngeal, to post. muscles of larynx. Tracheal Brs. to trachea, anas. Bronchial. Esophageal Brs. to cesophagus. Ascending Cervical, to muscles, spinal cord. Muscular. to muscles of hvoid bone and of

Transversalis Colli.

the pharynx.

Superficial Cervical, beneath Trapezius.

Posterior Scapular, along post. border.

Supra-acromial, anas. Acromial Thoracic.

Supra-sternal, to skin of the chest.

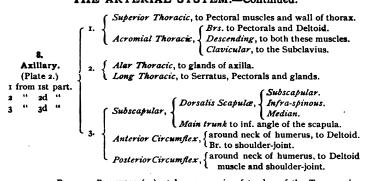

Supra-scapular.

Muscular, to sterno-mastoid, etc.
Nutrient, to the clavicle.

7.
INTERNAL
MAMMARY.
(Plate 1.)

Comes Nervi Phrenici (Superior Phrenic), to Diaphragm.
Mediastinal Brs. to tissue and glands, ant. mediastinum.
Pericardiac Brs. to upper part of pericardium.
Sternal Brs. to sternum and Triangularis sterni.
Anterior Intercostals, to 5 or 6 upper intercostal spaces.
Perforating, to Pectoralis major, mammary gland, etc.

Musculo-phrenic {Ant. Intercostals, to lower intercostal spaces.
Brs. to lower pericardium, Diaphragm, etc.
Superior Epigastric {ans. with deep Epigastric of Ext. Iliac.
supplies abdominal muscles and skin.

Becomes Brachial (10), at lower margin of tendon of the Teres major muscle.

9.
Brachial.
(Plate 2.)

Superior Profunda, 

Superior Profunda, 

Main trunk, in spiral groove of the humerus, to Deltoid, Triceps, etc.

Nutrient, to nutrient canal of the humerus.

Inferior Profunda, to the elbow-joint anastomosis.

Anastomotica Magna, transversely inward on Brachialis anticus muscle to the elbow, where it anastomoses with several arteries.

Muscular, 3 or 4, to muscles in course of artery.

Bifurcates into RADIAL (10) and ULNAR (11).

I.

Radial Recurrent, anas. branches of Sup. profunda.

Muscular Brs. to muscles on radial side of arm.

Ant. Carpal, to wrist-joints, anas. Ant. Carpal of Ulnar.

Superficialis Volæ, to muscles of the thumb.

Post. Carpal, {to wrist-joints, anas. Post. Carpal of Ulnar.

Dorsal Interosseous, for 3d and 4th spaces.

Metacarpal, is the First Dorsal Interosseous Branch.

Dorsales Pollicis 2, laterally on dorsum of thumb.

Dorsalis Indicis, on radial side of index dorsum.

Princeps Pollicis, 2 Brs. forming arch on last phalanx.

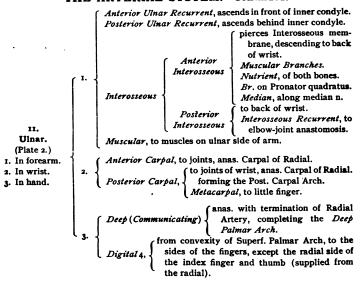

Radialis Indicis, along radial side of index finger.

Perforating 3 between heads of last Dorsal Interossei.

Palmar Interosseæ { 3 or 4 along Interossei muscles, given off by Deep Palmar Arch.

Palmar Recurrent, to the carpal articulations.

Forms Deep Palmar Arcm in the hand, completed by inosculation with the Deep Palmar (Communicating) from the Ulnar Artery.

Forms SUPERFICIAL PALMAR ARCH in palm of hand, by inosculating with a branch from the Radialis Indicis of the Radial Artery.

Pericardiac Branches, distributed to the pericardium.

Bronchial Arteries 3 nutrient vessels of the lungs.

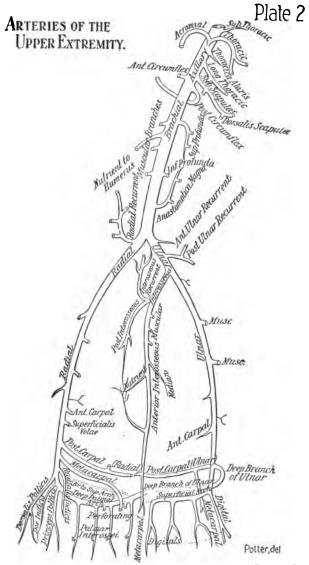

Esophageal, 4 or 5, anas. brs. Inf. Thyroid, Phrenic, Gastric.

Posterior Mediastinal, (several) to glands, etc., in mediastinum.

Posterior (Dorsal), to muscles of back.

Spinal, to the spinal cord and its membranes.

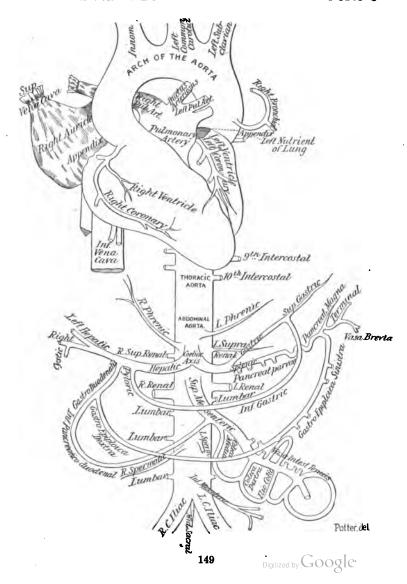

Collateral Intercostal, along upper border of the next rib below.

Internal, to front of thorax and Diaphragm. Phrenic, External, to side of thorax. to cardiac orifice of stomach, cardiac end, then along lesser curvature to Gastric, pylorus, where it anas. with Pyloric Br. of Hepatic Art. Pyloric, to pylorus, anas. Gastric Art. Gastro-epiploica Gastro-duoden-Dextra. Pancreatico-duo-Hepatic, denalis. CORLIAC to right lobe. Axis. Right Hepatic, Cystic, to gallbladder. Left Hepatic, to left lobe of liver. Pancreaticæ Parvæ \ to the pan-Pancreatica Magna creas. Gastric (Vasa Brevia), 5 to 7, to the Splenic. greater curvature of stomach. Gastro-epiploica Sinistra, along the greater curvature, from left to right. Terminal Brs. enter hilum of Spleen. Inferior Pancreatico-duodenal, to those organs. Vasa Intestini Tenuis 12 to 15, form arches in mesentery, in several series, from terminal arches branches ramify on intestines. Reo-colic, { Inferior, anas. Vasa intes. ten. Superior, anas. Colica dextra. Superior Mesenteric. Colica Dextra { Desc. Br. } Arches branching to Asc. Br. } ascending colon. Colica Media  ${Right \atop Left}$  Arches, branching to transverse colon. Supra-renal, to supra-renal capsule. f Brs. to substance of kidney. Small Brs. to capsule, ureter, etc. Spermatic (or Ovarian) to testes or ovaries, uterus, etc. Colica Sinistra Asc. Arches branching to descending colon. Inferior Sigmoid, across Psoas to that flexure of colon. Mesenteric. (Plate 4.) Sup. Hemorrhoidal,  ${Br. \text{ to right} \atop Br. \text{ to left}}$  side of rectum.  $\begin{cases}
Dorsal & \text{fto muscles, etc., of back.} \\
Spinal, \text{to canal} & Br. \\
Br. & \text{Arches.}
\end{cases}$ Abdominal, between abdominal muscles. Middle Sacral, to coccyx, anas. Lateral Sacral. RIGHT COM. ILIAC, R. Int. and Ext. Iliac (14, 15). LEFT COM. ILIAC, L. Int. and Ext. Iliac (14, 15). Bifurcation occurs at 4th Lumbar Vertebra, opposite Umbilicus, Digitized by GOOTIC

Abdominal
Aorta.
(Plate 3.)

## BRANCHES OF THE AORTA

Superior Vesical { Art. of Vas Deferens, to that organ. Middle Vesical, to base of bladder. Riac, to iliac bone and Iliacus muscle. Vesical, backward to the bladder. Public, on the back of the public bone.

Internal, along inner margin obturator foramen.

External, {outer margin obturator foramen.

Br. to hip-joint by cotyloid notch. Inferior Vesical, to base of bladder, prostate gland, etc. Middle Hemorrhoidal, to anus, anas, other hem. arteries. Br. to the bladder. Br. to the ureter.
Cervical, to neck of uterus. In the female. Azvgos, of the vagina. Vaginal, analogous to Inf. Vesical of male. Inferior Hemorrhoidal, 2 or 3 to the anus. Superficial Perinæal, to the scrotum, etc. Transverse Perinæal, to muscle of same name. Artery of the Bulb, large but very short. Artery of the Corpus Cavernosum, to that body.

14 a.
Internal Iliac.
ANTERIOR
TRUNK.
(Plate 4.)

Muscular Brs. within the pelvis.

Hemorrhoidal Brs. to the rectum.

Vesical Brs. to base and neck of bladder.

Coccygeal, to back of coccyx.

Inf. Gluteal 3 or 4, to Gluteus maximus.

Comes Nervi Ischiadici, along sciatic nerve.

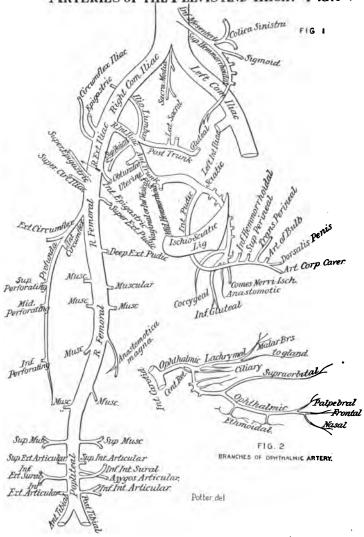

Muscular Brs. to back of hip.

Anastomotic, to the crucial anastomosis.

Articular Brs. to capsule of the hip-joint.

Dorsal Artery of the Penis, thereto.

ARTERIES OF THE PELVIS AND THIGH. Plate 4

```
Itab.

Internal Iliac.
POSTERIOR
TRUNK.
(Plate 4.)

Internal Iliac.

Gluteal,

Internal Iliac.

Posterior Lateral Sacral, to dorsum of sacrum.

Inferior Lateral Sacral, to front of sacrum, and coccyx, anas with Sacra media, etc.

Muscular Brs. within the pelvis.

Nutrient, of the Ilium.

Superficial, to Gluteus maximus, etc.

Deep Superior, to ant. sup. spine of Ilium.

Inferior, to glutei and hip-joint.
```

Muscular Brs. several, to Psoas and glands.

External Iliac.
(Plate 4.)

Epigastric, Cremasteric, to cremaster muscle.
Pubic, to inner side of femoral ring.
Muscular, to abdominal muscles and skin.

Circumflex Iliac, betw. Transversalis and Int. oblique.
Br. anas. with Lumbar and Epigastric.

Becomes Femoral (16) at Poupart's Ligament.

Superficial Epigastric, in superf. fascia, to umbilicus.
Superf. Circumflex Iliac, outward to iliac crest.
Superf. Ext. Pudic, inward to skin of penis, scrotum, etc.
Deep Ext. Pudic, inward to skin of perineum, etc.

[Asc. Brs. outer side of hip. Transverse, to back of hip. Descending, as far as knee.
[Ascending, to Adductors, etc. Descending, to Adductors, etc. Articular, to head of femur.

[Plate 4.]

[Profunda Femoris, Middle, Nutrient of Femur.

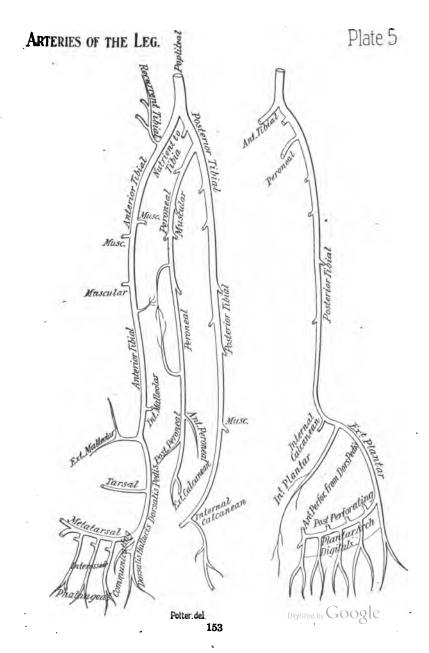

[Inferior, pierces Adductor magnus.

[Perforating, Middle, Nutrient of Femur.

[Inferior, pierces Adductor magnus.

[Superficial Br. to integument.
[Deep Br. to inner side of knee and joint, anas: with Sup. Articulars and Recurrent br. of Anterior Tibial.

Becomes POPLITEAL (17), at opening in Adductor magnus.

Muscular Superior Brs. to Vastus ext. and flexor muscles.
Inferior or Sural 2, to Gastrocnemius and Plantaris.
Cutaneous Brs. to integument of calf.
Superior Internal Articular, to Vastus int. and joint.
Superior External Articular, to Vastus ext. and joint.
Azygos Articular, to synovial membrane of joint.
Inferior External Articular, to head of tibia and joint.
Inferior External Articular, to front of knee-joint.

Bifurcates into { ANTERIOR TIBIAL (18) } at lower border of Popliteus Posterior Tibial (19) } muscle.

Post. Recurrent Tibial, to the Popliteus muscle.

Superior Fibular, to the Soleus and Peroneus longus.

Ant. Recurrent Tibial, to the knee-joint anastomosis.

Muscular Brs. numerous to muscles of leg.

Internal Malleolar, beneath tendon of Tibialis anticus.

External Malleolar, to outer ankle.

(Plate 5.)

Dorsalis Pedis

Dorsalis Hallucis { Brs. to great toe.}

Br. to inner side of 2d toe

Communicating, { anas. Ext. Plantar (Arch).}

2 Digital Brs.

Ends in the PLANTAR ARCH.

Anterior Peroneal, pierces interosseous membrane.

Posterior Peroneal, to the os calcis.

Nutrient Artery of the fibula.

Muscular, several brs. in its course.

Communicating { joins similar branch of the posterior Tibial.

Ext. Calcanean, the terminal branches.

Nutrient of Tibia, the largest nutrient artery of bone.

Communicating Br. to a similar br. of the Peroneal.

Internal Calcanean Brs. to the heel, and sole of foot.

Internal Plantar, along inner side of foot and great toe.

External Plantar,

Posterior Perforating 3 Branches.

4 Digital, { Ant. Perforating Branches.

Ends as the PLANTAR ARCH, anas. with Commun. Br. of Dorsalis Pedis.

#### THE VEINS.

Veins are vessels which return the blood from the capillaries of the body to the heart. Their walls, like those of the arteries, are composed of 3 coats—an internal serous, a middle muscular, and an external one of connective tissue. Their middle coat is weaker than that of the arteries, so that they do not stand open when divided, as the arteries do. They all carry carbonized (venous) blood, except the pulmonary veins, which bring oxygenated blood to the left side of the heart. The deep veins accompany the arteries, generally in the same sheath, and are given the same names. The secondary arteries, as the radial, ulnar, brachial, etc., have each two veins, called Vena Comites. The superficial veins are usually unaccompanied by arteries, and lie, as a rule, between the layers of the superficial fascia, terminating in the deep veins. Many veins are so irregular in their origin that they cannot be accurately described; they all anastomose with each other much more freely than do the arteries.

Sinuses are venous channels, differing from veins in structure, but answering the same purpose. Those of the cranium are formed by the separation of the layers of the dura mater.

The Veins are divided into the *Pulmonary*, Systemic, and Portal Systems; the latter being an appendage of the systemic, its capillaries ramifying in the liver.

Veins having no valves are the venæ cavæ, hepatic, portal, renal, uterine, ovarian, cerebral, spinal, pulmonary, umbilical, and the very small veins.

The Pulmonary Veins alone of the veins carry arterial blood, beginning in the capillaries of the lungs, forming a single trunk for each lobule, which, uniting into a single trunk for each lobe, form two main trunks from each lung which open separately into the left auricle. Sometimes the three lobe-trunks of the right lung remain separate to their termination in the auricle, and not unfrequently a common opening serves for the two left pulmonary veins.

#### VEINS OF THE HEAD AND NECK.

#### Exterior Veins of the Head and Face are as follows,-

Frontal Vein,—begins on the anterior part of the skull by a venous plexus converging to a single trunk near the middle line of the forehead, which joins the supra-orbital vein at the root of the nose to form the angular vein. Supra-orbital Vein,—begins on the forehead and joins the frontal (see above) to form the angular vein.

Ingular Vein,—formed as described above, runs downward and outward on

- the side of the root of the nose, communicates with the ophthalmic vein, and ends in the—
- Facial Vein,—a direct continuation of the angular, begins at the side of the root of the nose, descends obliquely across the masseter muscle and over the body of the lower jaw to unite with the ant. division of the temporomaxillary to form the common [acial vein, which enters the internal jugular.
- Temporal Vein,—begins on the vertex and side of the skull, by anterior and posterior branches which unite and are joined by the middle temporal above the zygoma to form the trunk, which descends through the parotid gland and unites with the internal maxillary to form the temporo-maxillary vein.
- Internal Maxillary Vein,—is formed by branches corresponding to those of the internal maxillary artery, forming the pterygoid plexus. The trunk passes backward behind the neck of the lower jaw and unites with the temporal to form the—
- Temporo-maxillary Vein,—descends in the parotid gland and divides into an anterior branch, which joins the facial, and a posterior branch which is joined by the posterior auricular and becomes the external jugular.
- Posterior Auricular Vein,—begins on the side of the head, descends behind the external ear and joins the posterior division of the temporo-maxillary, forming the external jugular.
- Occipital Veins,—begin in a plexus at the back of the head and terminate in the internal jugular.

## Veins of the Diploë and Interior of the Cranium,-

- Veins of the Diploē,—a number of tortuous canals lying between the two tables of the skull, and divided into frontal, anterior temporal, posterior temporal and occipital branches.
- Cerebral Veins,—have no muscular coat and no valves. They are divided into superficial and deep sets. The deep cerebral are formed by the union of the vena corporis striati and the choroid vein on either side, and receive the basilar vein.
- Cerebellar Veins,—on the surface of the cerebellum, are disposed in 3 sets, superior, inferior and lateral.
- Superior Longitudinal Sinus,—occupies the attached margin of the falx cerebri, begins at the foramen cæcum, and ends in the torcular Herophili, or confluence of the sinuses.
- Inferior Longitudinal Sinus,—in the free margin of the falx cerebri posteriorly, terminates in the—
- Straight Sinus,—at the junction of the falx cerebri with the tentorium, terminates in the lateral sinus of the opposite side.

Lateral Sinuses,—in the attached margin of the tentorium cerebelli, terminate in the internal jugular vein.

Occipital Sinus,—in the attached margin of the falx cerebri, terminates in the torcular Herophili.

Cavernous Sinuses,—one on each side of the sella turcica, receives the ophthalmic vein and opens behind into the petrosal sinus.

Circular Sinus,—is formed by two transverse vessels, the anterior and posterior intercavernous sinuses, connecting the two cavernous sinuses, and forming a venous circle around the pituitary body.

Superior Petrosal Sinus,—connects together the cavernous and lateral sinuses of each side.

Inferior Petrosal Sinus,—begins at the termination of the cavernous sinus, and joins the lateral sinus to form the internal jugular vein.

Transverse or Basilar Sinus,—connects the two inferior petrosal sinuses over the basilar process of the occipital bone.

Emissary Veins,—pass through apertures in the cranial wall from the sinuses inside to the veins outside; the principal ones being 8 in number.

Veins of the Neck, draining those above-mentioned, are the-

External Jugular (6),—terminating in the subclavian vein (4).

Posterior External Jugular, - opens into the external jugular.

Internal Jugular (7),—enters the subclavian vein near the external jugular.

Internal Jugular (5),—formed by the junction of the two last-named sinuses at the jugular foramen, and uniting with the subclavian vein to form the innominate, at the root of the neck. In its course it receives the facial, lingual, pharyngeal, superior and middle thyroid veins, and the occipital.

Vertebral,—descends the foramina in the transverse processes of the cervical vertebræ, and empties into the innominate vein. In its course it receives the anterior and posterior vertebral and many other veins.

#### VEINS OF THE UPPER EXTREMITY.

Veins of the Hand, Forearm, and Arm are in two sets superficial and deep. The superficial set lies in the superficial fascia, begin in the hand by external and internal dorsal and superficial palmar veins, and are continued as follows, the basilic continuing as the axillary, which receives the cephalic just below the clavicle.

Dorsal.	Radial	
Palmar.	Median { Median Cephalic } Cephalic } A	XIL-
Dorsal. {	Radial	EIN.

The deep veins follow the arteries, generally as venæ comites, beginning in the hand as Digital, Interosseous and Palmar veins, they unite in the Deep Radial and Deep Ulnar, which join to form the Venæ Comites of the brachial artery at the bend of the elbow. The Brachial Veins lie one on each side of the brachial artery and join the Axillary Vein. These deep veins have numerous anastomoses, not only with each other but also with the superficial ones.

> Axillary Vein,—the continuation of the basilic, lies on the inside of the artery and terminates beneath the clavicle at the outer border of the 1st rib, where it becomes the-Subclavian Vein,-the continuation of the axillary, extends from the outer border of the 1st rib to the inner end of the clavicle, where it unites with the internal jugular to form the innominate vein. At the angle of junction enters the thoracic duct on the left side of the body and the right lymphatic duct on the right side. In its course it receives the external and anterior jugular veins and a branch from the cephalic.

The Innominate Vein is formed by the union of the subclavian and the internal jugular. The two innominates unite just below the 1st costal cartilage to form the superior vena cava. The Right Innominate (3) is about 1 inch long, and receives, besides its constituent branches, the right internal mammary, right inferior thyroid, and right superior intercostal veins. The Left

Innominate (2) is about 21 inches long; in its course it receives the vertebral, inferior thyroid, internal mammary, and superior intercostal veins of the left side.

#### VEINS OF THE THORAX.

The Veins of the Thorax include the following vessels;-

Internal Mammary,-two to each artery, unite into a single trunk which terminates in the innominate vein.

Injerior Thyroid,—2 to 4, form a plexus in front of the trachea, which gives

off the left and right inferior thyroid veins, these receiving œsophageal, tracheal and inferior laryngeal veins and opening into the innominate veins.

Superior Intercostal,—the right vein opens into the vena azygos major, the left vein into the left innominate.

Azygos Veins, - are described below.

Bronchial,—return the blood from the lung substance; the right one opens into the vena azygos major, the left into the left superior intercostal or the left upper azygos vein.

Spinal,—are described below.

Venæ Cavæ,—are described below; the Superior Vena Cava under the Veins of the Thorax, the Injerior Vena Cava under the Veins of the Lower Extremity.

The Azygos Veins supply the place of the venæ cavæ in the region where these trunks are deficient, being connected with the heart.

Right Azygos (17),—begins by a branch from the right lumbar veins usually, passes through the aortic opening in the diaphragm, and ends in the superior vena cava, having drained 10 right lower intercostals, the vena azygos minor, the right bronchial, œsophageal, mediastinal, and pericardial veins.

Left Lower Azygos (18),—begins by a branch from the left lumbar or renal, passes through the left crus of the diaphragm, crosses the vertebral column and ends in the right azygos, having drained 4 or 5 lower intercostals.

Left Upper Azygos,—drains 3 or 4 left intercostals and empties into either of the other two. It is often wanting, its place being filled by the left superior intercostal vein (21).

The Spinal Veins may be arranged in 4 sets, as follows:—

Dorsi-spinal,—form a plexus around the spines, processes, and laminæ of all the vertebræ. They empty into the vertebral, intercostal, lumbar, and sacral veins in their respective regions.

Meningo-rachidian,—in two longitudinal plexuses, anterior and posterior, running the whole length of the spinal canal. The posterior join the dorsi-spinal veins, the anterior empty into the vertebral, intercostal, lumbar, and sacral veins in their various regions.

Venæ Basis Vertebrarum,—the veins of the bodies of the vertebræ, are contained in large, tortuous channels in the substance of the bones, and join the transverse trunk connecting the anterior longitudinal veins.

Medulli-spinal,—the veins of the spinal cord, lie in plexus form between the pia mater and arachnoid. They unite into 2 or 3 small trunks near

the base of the skull, which terminate in the inferior cerebellar veins or in the inferior petrosal sinuses.

The Superior Vena Cava (1) is a short trunk about 2½ or 3 inches in length, formed by the union of the two innominate veins, thereby receiving all the blood from the upper half of the body, and opening into the right auricle of the heart. It is half covered by the pericardium, and receives the vena azygos major and small pericardiac and mediastinal veins.

#### VEINS OF THE LOWER EXTREMITY.

The Veins of the Lower Extremity are in two sets, superficial and deep. The superficial are the—

Internal or Long Saphenous,—on the inside of the leg and thigh, enters the femoral at the saphenous opening 1½ inch below Poupart's ligament. In its course it receives:—

Cutaneous Branches.

Superficial Circumflex Iliac.

Superficial Epigastric. Ext. Pudic. Communicating Branches.

External or Short Saphenous,—formed by branches from the dorsum and outer side of the foot, it ascends behind the outer malleolus, up the middle of the back of the leg, and empties into the popliteal vein, between the heads of the gastrocnemius muscle.

The deep veins are the venæ comites of the arteries, beginning in the foot as the external and internal Plantar, which unite to form the Posterior Tibial. The venæ comites of the dorsalis pedis artery continue upward as the Anterior Tibial veins, which join the posterior tibial, forming the—

Popliteal,—which becomes the Femoral, and it the External Iliac, in the same manner as the respectively-named arteries.

#### VEINS OF THE PELVIS AND ABDOMEN.

The Veins of the Pelvis, except the middle sacral, open into the internal iliac vein. The middle sacral opens into the left common iliac.

The Internal Iliac Vein (10) is formed by the venæ comites of the branches of the internal iliac artery, and terminates with the external iliac, at the sacro-iliac articulation, to form the common iliac vein. It receives the following veins:—

From the exterior of the pelvis, the-

Gluteal. Sciatic. Internal Pudic. Obturator.

From the organs in the pelvic cavity the—

The Dorsal Vein of the Penis enters the prostatic plexus.

The Veins of the Abdomen include the Portal System, the Lumbar, Spermatic, Renal, Suprarenal, Phrenic, Hepatic, External Iliac Common Iliac and the Inferior Vena Cava.

The External Iliac Vein commences at the termination of the femoral beneath Poupart's ligament, and terminates opposite the sacro-iliac synchondrosis by uniting with the internal iliac to form the common iliac vein. It receives the *Deep Epigastric* and *Deep Circumflex Iliac*, also a small pudic vein.

The Common Iliac Veins (11) are each formed by the union of the two iliac veins as above described, and unite between the 4th and 5th lumbar vertebræ to form the inferior vena cava, the right common iliac being the shortest of the two. Each receives the *Ilio-lumbar*, sometimes the *Lateral Sacral*, and the left one in addition the *Middle Sacral Vein*, which sometimes ends in the vena cava.

The Inferior Vena Cava (8) extends from the junction of the two common iliac veins, passing along the front of the spine, through the tendinous centre of the diaphragm, to its termination in the right auricle of the heart. It receives the following veins:—

Lumbar (12),—4 on each side, receive dorsal and abdominal tributaries, also veins from the spinal plexuses, and terminate in the inferior vena cava. They are connected together by the ascending lumbar, which passes in front of the transverse processes of the lumbar vertebræ.

Right Spermatic (13).—The spermatic veins arise from the testis and epididymis, forming the spermatic or pampiniform plexus, which forms the chief mass of the spermatic cord, and unite into 3 or 4 veins which enter the abdomen through the internal ring, form 2 veins, then a single one which opens on the right side into the inferior vena cava, on the left side into the left renal vein. In the female they are called Ovarian and terminate in the same way as in the male.

Renal (15),—are large veins, placed in front of the renal arteries, and terminating in the inferior vena cava. The left is longer than the right and passes in front of the aorta.

Supra-renal,—on the right side ends in the vena cava, on the left side in the left renal or phrenic vein.

Phrenic 2,—the superior ends in the internal mammary, the inferior ends on the right side in the vena cava, on the left side in the left renal vein.

Hepatic Veins (16),—begin in the capillary terminations of the portal vein and hepatic artery in the substance of the liver, uniting into 3 large veins from the right and left lobes and the lobulus Spigelii, which open into the inferior vena cava. They have no valves.

The Portal System is formed by the Superior and Inferior Mesenteric, Splenic, and Gastric Veins, which collect the blood from the digestive viscera, and by their union behind the head of the pancreas form the Portal Vein, which enters the transverse fissure of the liver, where it divides into 2 branches. These again subdivide, ramifying throughout the organ, therein receiving blood also from the branches of the hepatic artery. Its minute ramifications end in capillaries, from which the blood of the portal system, together with that brought by the hepatic artery is carried by the hepatic veins to the inferior vena cava. The portal vein generally receives the Cystic Vein, which sometimes terminates in the right branch of the portal.

#### VEINS OF THE HEART ITSELF.

The Cardiac Veins return the blood from the tissue of the heart into the right auricle. They are the—

Great Cardiac Vein.

Right or Small Coronary Vein.

Posterior Cardiac Vein.

Anterior Cardiac Veins.

Lest Cardiac Veins.

Venæ Thebesii.

Coronary Sinus, is a dilatation of the great cardiac vein, receiving the posterior cardiac and an oblique vein from the left auricle.

## THE LYMPHATIC SYSTEM.

Lymphatics are very delicate, transparent vessels; the larger having 3 coats like the arteries and veins, the smaller having 2 coats, the external and internal, but no middle muscular-elastic coat. Lymphatics are found in nearly every texture and organ of the body which contains blood-vessels, but are absent in the non-vascular structures, as cartilage, nails, cuticle and hair. They are nourished by blood-vessels distributed to their outer and middle coats, in which also many non-medullated nerve-fibres have been traced. They possess valves of semilunar form, placed at much shorter intervals than are the valves in the veins. They convey lymph to the blood, and possess the property of absorbing certain materials from the tissues and conveying them into the circulation; hence they are also called absorbents. They discharge their contents into the blood at two points, the junctions of the subclavian and internal jugular veins, on the left side by the thoracic duct, on the right side by the right lymphatic duct.

Lacteals are the lymphatic vessels of the small intestine, conveying *chyle* to the blood during the process of digestion.

Lymphatic Glands are small, solid, glandular bodies, placed in the course of the lymphatic and lacteal vessels, and found chiefly along the great

bloodvessels, at the root of the lungs, in the lumbar and cœliac regions of the abdomen, in the mesentery, the mediastina, the head, neck, axilla, groin, and popliteal space. They are named after the respective regions in which they are situated, as the axillary glands, the inguinal, cœliac, bronchial, mesenteric, etc. They consist of a fibrous capsule, from which trabeculæ are prolonged inward, dividing the gland into alveoli or open spaces containing lymphoid tissue, the proper gland-substance, which is so placed as to leave a channel, the lymph-path, all around it. The glands are nourished by bloodvessels supported on the trabeculæ, and some fine nerve filaments are traced into them.

Before entering a gland the lymphatic (or lacteal) divides into several small branches, the afferent vessels, of which the endothelial layer only enters the gland, to form in its lymph-sinuses a plexus of vessels which unite into a single efferent vessel. The external coat of the afferent vessels becomes continuous with the capsule of the gland, and is received upon the efferent vessel as it emerges.

The Thoracic Duct is the main channel for the lymph and chyle from the whole body except the right arm and lung, right side of the head, heart, neck, and thorax, and the convex surface of the liver. It begins in the abdomen by a triangular dilatation, the—

Receptaculum Chyli, in front of the 2d lumbar vertebra, passes through the aortic opening in the diaphragm, and opposite the 7th cervical vertebra it curves forward, outward and downward over the subclavian artery, so as to form an arch, and terminates in the left subclavian vein at its angle of junction with the left internal jugular vein. In the thorax it lies in the posterior mediastinum in front of the vertebral column, between the aorta on its left and the vena azygos major on its right. It has numerous valves throughout its course, and a pair of valves at its termination to prevent the passage of venous blood into its cavity.

The Right Lymphatic Duct is a short trunk, about ½ inch in length and 1½ line in diameter. It terminates in the right subclavian vein at its angle of junction with the right internal jugular, its orifice being guarded by two semilunar valves against the passage of venous blood into its cavity. It receives lymph from those parts which are not connected with the thoracic duct, namely—the right upper extremity, the right lung, the right side of the head, neck, heart and thorax, and part of the convex surface of the liver.

LYMPHATICS OF THE HEAD AND NECK.

Lymphatic Glands of the Head and Neck, are as follows:—
Occipital, 1 or 2,—at the back of the head, close to the artery.

Posterior Auricular or Mastoid, 2,—near the mastoid process.

Parotid,—some in and others around the parotid gland.

Buccal, I or more,—on the surface of the buccinator muscle.

Internal Maxillary, -beneath the ramus of the jaw.

Lingual, 2 or 3,—on the hyo-glossus and genio-hyo-glossus muscles.

Retro-pharyngeal, 2,—one on each side of the middle line.

Superficial Cervical,—consisting of the submaxillary, 8 to 10, the suprahyoid, 1 or 2, and the cervical (many) in the course of the external jugular vein.

Deep Cervical,—forming a chain along the sheath of the carotid artery and internal jugular vein, in two sets, an upper, 10 to 20, and a lower, 10 to 15.

Lymphatic Vessels of the Head and Neck are—the Temporal and Occipital, in the scalp, respectively accompanying the temporal and occipital arteries; the Meningeal and Cerebral, in the cranium; the Superficial and the Deep, in the face; also those of the orbit, the temporal and zygomatic fossæ, the nose, tongue, pharynx, larynx and thyroid body. In the neck these vessels are continuations of those on the cranium and face.

#### LYMPHATICS OF THE UPPER EXTREMITY.

Lymphatic Glands of the Upper Extremity are in two sets, the Superficial, which are few and small, and the Deep, in the forearm, the arm and the axilla. The Axillary Glands, 10 to 12, are of large size, situated around the axillary vessels, in the tissue of the axilla, and in chains along the lower border of the pectoralis major muscle and the lower margin of the posterior wall of the axilla.

Lymphatic Vessels of the Upper Extremity are the Superficial, beginning on the sides of the fingers and accompanying the veins; the Deep, occurring in 4 sets corresponding with the radial, ulnar, and anterior and posterior interosseous arteries.

#### LYMPHATICS OF THE LOWER EXTREMITY.

Lymphatic Glands of the Lower Extremity are the—Superficie Inguinal, 8 to 10, in two sets, an upper oblique set along Poupart's ligament, and an inferior vertical set, 2 to 5, around the saphenous opening in the fascia lata; Deep Glands are the anterior tibial, popliteal, deep inguinal, gluteal and ischiatic.

Lymphatic Vessels of the Lower Extremity are in two sets, superficial and deep. The Superficial lie in the superficial fascia in two groups, an internal and an external, along the internal and external saphenous veins

respectively. The *Deep* are few in number and accompany the deep blood-vessels.

#### LYMPHATICS OF THE PELVIS AND ABDOMEN.

Lymphatic Glands are the external iliac, internal iliac, and sacral, in the pelvis; and the lumbar and cœliac glands in the abdomen. The Lumbar Glands are numerous, situated in front of the lumbar vertebræ, and surround the common iliac vessels, the aorta and the vena cava. The Cœliac Glands 20, surround the cœliac axis and lie in front of the aorta, receiving the lymphatic vessels from a large part of the liver, the spleen, pancreas and stomach.

Lymphatic Vessels of the Pelvis and Abdomen are in 3 sets, the superficial, the deep, and those of the viscera. The Superficial follow the course of the superficial bloodvessels, and include the lymphatics of the gluteal region, the penis, scrotum and perinæum. The Deep follow the course of the principal bloodvessels. Those of the Viscera are the lymphatics of the various organs contained in these cavities—the bladder, rectum, uterus, kidney, liver, stomach, spleen and pancreas, and include those of the testicles.

#### LYMPHATICS OF THE INTESTINES.

Lymphatic Glands of the Intestines are those of the large intestine, which are few in number, especially along the transverse colon; and those of the small intestine, 100 to 150, which lie between the layers of the mesentery and are called the *Mesenteric Glands*.

Lymphatic Vessels of the Intestines are those of the large intestine, some of which enter the mesenteric glands, others the lumbar glands; and those of the small intestine, called the *Lacteals*, from the milk-white fluid (chyle) which they usually contain. The lacteals are in two sets, superficial and deep, the latter occupying the submucous tissue and coursing transversely around the intestine.

#### LYMPHATICS OF THE THORAX.

Lymphatic Glands of the Thorax are those of the thoracic walls and those of the viscera. The former are the intercostal, the internal mammary, and the anterior and posterior mediastinal glands: the latter are the bronchial and the superior mediastinal or cardiac glands. The—

Bronchial Glands, 10 to 12,—are situated around the bifurcation of the trachea and the roots of the lungs.

Superior Mediastinal or Cardiac Glands,—are numerous and large, lie in front of the transverse aorta and the left innominate vein, and receive the lymph from the pericardium, the heart, and the thymus gland.

Lymphatic Vessels of the Thorax are the superficial, the deep and those of the viscera in the thoracic cavity. The Superficial converge to the axillary glands; the Deep are the intercostal, the internal mammary and the diaphragmatic; those of the Viscera are the lymphatic vessels of the lungs, heart, thymus gland and cesophagus.

## THE NERVOUS SYSTEM.

Nervous Tissue is formed of two different structures, viz. Gray or cineritious substance, in which nervous impressions and impulses originate; and White or fibrous substance, by which the impressions and impulses are conducted. Chemically, nervous tissue consists of proteids, neurokeratin, nuclein, protagon, lecithin, cerebrosides, cholesterin, nitrogenous extractives and salts, with some gelatin and fat, and water; the latter varying in different parts of the system, from 60 per cent. in the sciatic nerve, to 70 per cent. in the white matter of the cerebrum, and 83 per cent. in the gray matter of the same region.

Gray Nervous Substance, the essential constituent of all the ganglionic centres, is composed of nerve-cells or ganglionic corpuscles, containing nuclei and nucleoli. The cells are imbedded in a ground substance, neuroglia, which consists of fibres and cells, and is a connective tissue in function though not in development. Nerve-cells vary in size and shape, and possess one or more processes, according to the number of which they are grouped into unipolar, bipolar and multipolar cells. Of these processes one is called the axon or axis-cylinder process, because it becomes the axis-cylinder of a nerve-fibre; the others are termed dendrons or protoplasmic processes

White Nerve Substance or Nerve Fibre, contains two kinds of fibres, the medullated or white and the non-medullated or gray. Medullated Fibres contain a central core or axis-cylinder, the essential part of the nerve-fibre, and regarded as a direct prolongation of a nerve-cell. This is surrounded by the medullary sheath, or white substance of Schwann, composed of fatty matter in a fluid state, which insulates and protects the axis-cylinder. These are enclosed in the primitive sheath or neurilemma, sometimes called the tubular membrane or sheath of Schwann, which is absent in the fibres found in the brain and spinal cord. A bundle or juniculus, of such fibres, held together by endoneurium, is surrounded by perineurium, both formed of delicate connective tissue; and several funiculi are collected into larger bundles, jasciculi, which are bound together by a common membrane, the epineurium, and then are called a Nerve. The whole arrangement is precisely analogous to that of a submarine telegraph cable. The nerve is

nourished by a minute system of capillary bloodvessels, and has certain medullated fibres in the epineurium, termed the *nervi nervorum*, or nerves of the nerves.

The Non-medullated Fibres, also called gray or gelatinous nerve-fibres, or fibres of Remak, consist of a central core or axis-cylinder enclosed in a nucleated sheath. They constitute most of the sympathetic nerves and include some of the cerebro-spinal.

Terminations of Nerves. Their origin or central termination occurs from the nerve centre by one or two roots, in the latter case sometimes widely apart from each other. The efferent nerve-fibres originate in the cells of the gray substance, the afferent fibres branch among the cells without uniting with them. The peripheral termination of sensory nerves seems to be in minute primitive fibrillæ or networks thereof; that of motor nerves in special terminal organs, variously named, as the end-bulbs of Krause, the tactile corpuscles of Wagner, the Pacinian corpuscles, the neuro-tendinous and neuro-muscular spindles, and the motorial end-plates of the striped or voluntary muscular fibre.

Ganglia are separate small aggregations of nerve-cells, connected with each other, with the cerebro-spinal axis, and with nerves in various situations. They consist of a collection of nerve-cells and nerve-fibres, invested by a membranous envelope, which is continuous with the perineurium of the nerves, and sends processes into the interior of the ganglion to support the bloodvessels supplying its substance. They are found on the posterior roots of all the spinal nerves; on the posterior (sensory) root of the 5th cranial nerve; on the facial, auditory, glosso-pharyngeal and pneumogastric nerves; also in a connected series along each side of the vertebral column anteriorly, forming the trunk of the sympathetic, and on the branches of that nerve.

Divisions of the Nervous System are two,—the Cerebro-spinal System, or nervous system of animal life, and the Sympathetic System, or nervous system of organic life. These may be subdivided as follows:—

CEREBRO-SPINAL SYSTEM.	Cerebro-spinal Axis Cranial Nerves. Spinal Nerves.	. { Brain. Spinal cord. } CEI	
Sympathetic System.	2 Gangliated Cords.  3 Great Plexuses. { Smaller Ganglia. Nerve-fibres.	Cardiac Plexus. Solar or Epigastric. Hypogastric Plexus.	Closely associated with the vessels, viscera and glands.

#### THE BRAIN.

Development of the Brain. At an early period of embryonic life the cerebro-spinal axis consists of a thin-walled tube, the *neural tube*, which becomes enlarged at its cephalic end, where constrictions appear, dividing this end into 3 *vesicles*, the anterior, middle and posterior. From these vesicles are developed the ventricles of the brain, the rest of the neural tube forming the central cavity of the spinal cord. Thickenings of the wall of the neural tube form the substance of the brain and spinal cord. The—

Anterior. Vesicle,—divides into an anterior and a posterior cavity; the former becoming the lateral ventricles, and with the parts around them being termed the prosen-cephalon, or cerebral hemispheres; the latter persists as the 3rd ventricle, which with the surrounding parts is called the thalamen-cephalon or inter-brain.

Middle Vesicle,—its cavity becomes the aqueduct of Sylvius, and with the parts developed around it constitutes the mesen-cephalon or mid-brain.

Posterior Vesicle,—its cavity becomes the 4th ventricle, and with the parts developed around it constitutes the epen-cephalon, cerebellum and pons, and the meten-cephalon, the medulla oblongata.

Structure of the Cerebrum. The cerebrum is composed of gray and white matter, the former disposed in two great groups,—that of the cerebral cortex and that in the basal ganglia.

The Gray Matter of the Cortex is composed of 6 alternating white and gray layers. The cortex is made up of nerve-cells and nerve-fibres. The Nerve-cells are arranged in 4 layers, named, from the surface inward, as follows: the molecular layer, the layer of small pyramidal cells, the layer of large pyramidal cells, the layer of polymorphous cells. In certain parts of the cortex this arrangement is variously departed from, as many as 9 layers being described in the cuneus. The Nerve-fibres are either medullated fibres or naked axis-cylinders embedded in a matrix of neuroglia.

The Basal Ganglia are a series of ganglionic masses in the base of each cerebral hemisphere, subjacent to the island of Reil, they and it constituting the oldest part of the hemisphere, the first to appear in the order of development. They are semi-detached local thickenings of the gray cortex, and are named as follows:—

Corpus Striatum,—composed of two nuclei, the caudate and the lenticular (described on page 178). Closely associated with it are certain fasciculi of white matter, the—

Internal Capsule (page 178). Anterior Commissure (page 179). External Capsule (page 178). Tænia Semicircularis (page 177).

 $\mathsf{Digitized}\,\mathsf{by}\,Google$ 

Claustrum,—a thin band of gray matter, described under the corpus striatum on page 178.

Nucleus Amygdalæ,—a thickening of the cortex of the apex of the temporal lobe, producing a bulge, the amygdaloid tubercle, in the roof of the extremity of the descending cornu of the lateral ventricle.

The Optic Thalamus, though in close proximity to the corpus striatum, is not placed among the basal ganglia of the hemispheres, being considered part of the thalamen-cephalon or inter-brain.

The White Matter consists of medullated fibres in bundles, arranged in the following 3 systems:—

PEDUNCULAR FIBRES,—connecting the hemispheres with the medulla oblongata and the cord. They are collected into the *crura cerebri* or cerebral peduncles, described on page 176.

Transverse or Commissural Fibres,—connect the two hemispheres. They are the transverse fibres of the corpus callosum, and the anterior and posterior commissures of the 3rd ventricle.

Association Fibres,—connect different structures in the same hemisphere; the short, connecting adjacent convolutions; and the long, connecting distant structures, as follows: the—

Uncinate Fasciculus,—from the frontal to the temporal lobe, across the bottom of the fissure of Sylvius.

Cingulum,—antero-posteriorly in the convolution of the corpus callosum, from the anterior perforated space to the hippocampus major.

Superior Longitudinal Fasciculus,—connects the frontal lobe with the occipital and temporal lobes.

Inferior Longitudinal Fasciculus,—connects the temporal with the occipital lobe.

Perpendicular Fasciculus,—connects the inferior parietal lobule with the 4th temporal convolution.

Fornix,—connects the hippocampal convolution with the corpus albicans and the optic thalamus.

#### THE MENINGES.

Membranes of the Brain are the dura mater, the arachnoid membrane, and the pia mater.

The Dura Mater is a dense fibrous membrane lining the interior of the skull, and forming the internal periosteum of the cranial bones. It is continuous with the dura mater of the spinal cord and with the perioranium, being prolonged to the outer surface of the skull through the various foramina

at its base. It sends 4 processes into the cavity of the skull for the support of the different parts of the brain, also several processes and prolongations through orifices and foramina in the skull for the protection of nerve trunks and vessels. It presents the following points for examination:—

Falx Cerebri,—an arched process into the longitudinal fissure of the brain vertically; contains in its upper and lower margins the superior and inferior longitudinal sinuses.

Tentorium Cerebelli,—a lamina of dura mater supporting the posterior lobes of the brain, and covering the upper surface of the cerebellum. It incloses the lateral and superior petrosal sinuses.

Falx Cerebelli,—projects between the lateral lobes of the cerebellum, from the tentorium to the foramen magnum.

Diaphragma Sella,—a horizontal process forming a small circular fold which almost covers the pituitary body and constitutes a roof for the sella turcica.

Pacchionian Bodies,—clusters of white granulations situated on the outer surface of the dura mater, near the longitudinal sinus, (see page 171).

The Arachnoid Membrane is a delicate envelope which covers the brain, lying between the dura mater and the pia mater, and being prolonged around the cranial nerves as far as their points of exit from the skull. The—

Anterior Subarachnoidean Space,—is the interval between the arachnoid and the pia mater at the base of the brain, where the former membrane extends across between the two temporal lobes.

Posterior Subarachnoidean Space,—is a similar interval between the hemispheres of the cerebellum and the medulla oblongata. These two spaces communicate with each other across the crura cerebelli.

Subarachnoid Space,—is the interval between the arachnoid and pia mater, forming the two large spaces mentioned above at the base of the brain, but small on the surface of the hemispheres. It is occupied by a spongy connective tissue, in the meshes of which the cerebro-spinal fluid is contained. It communicates with the general ventricular cavity of the brain by 3 openings, one of which, the *Joramen of Magendie*, is in the middle line at the lower boundary of the 4th ventricle.

Subdural Space,—is the space between the arachnoid and the dura mater. It contains a small amount of fluid of the nature of lymph.

Cerebro-spinal Fluid,—occupies the subarachnoid space of the brain and spinal cord, and also the ventricular cavities of the brain. Its average quantity is about 2 oz., being most abundant in old persons. It forms a water-bed for the protection of the nervous centres from the effects of concussions.

Glandulæ Pacchioni or Pacchionian bodies,—are numerous, small granulations, which are not glandular in structure but enlarged normal villi of the arachnoid; found on the outer and inner surfaces of the dura mater, in the superior longitudinal sinus, and on the pia mater. They are not usually found until after the 7th year of age, and are occasionally wanting.

The Pia Mater is a vascular membrane, supplied by branches of the internal carotid and vertebral arteries. It covers the surface of the brain, dipping down into all the sulci, and forms the velum interpositum and choroid plexuses of the lateral and 4th ventricles. It consists of a minute plexus of bloodvessels, held together by a very fine areolar tissue; and contains numerous lymphatic vessels and nerves, the latter being derived from both the cerebro-spinal and sympathetic systems.

Weight of the Brain. Its average weight in the male adult is 40½ oz., in the female 44 oz., of which the cerebrum is about seven-eighths. The extreme weights in 278 male cases were 65 oz. and 34 oz.,—in 191 female cases, 56 oz. and 31 oz.

Divisions of the Brain. The Brain may be divided into the Cerebrum, the Cerebellum, the Pons Varolii and the Medulla Oblongata; but for the descriptive purposes it is best considered under the following 5 divisions, viz. the—

Cerebral Hemispheres or Prosen-cephalon,—comprising the various lobes, the lateral and 5th ventricles, and the basal ganglia.

Inter-brain or Thalamen-cephalon,—the region of the 3rd ventricle, including also the optic thalami and the pineal gland.

Mid-brain or Mesen-cephalon,—comprising the crura cerebri, the corpora quadrigemina, one of the corpora geniculata, and the aqueduct of Sylvius.

Hind-brain or Epen-cephalon,—comprising the pons Varolii, the cerebellum, and the upper half of the 4th ventricle.

Medulia Oblongata or Meten-cephalon,—including the lower half of the 4th ventricle.

### THE CEREBRAL HEMISPHERES.

# Lobes in each Hemisphere, are as follows:—

Frontal Lobe,—bounded internally by the longitudinal fissure, below by the fissure of Sylvius, and posteriorly by the fissure of Rolando.

Parietal Lobe,—extending down to the fissure of Sylvius, and antero-posteriorly from the fissure of Rolando to the parieto-occipital fissure.

Occipital Lobe, - behind the parieto-occipital fissure.

 $\mathsf{Digitized}\,\mathsf{by}\,Google$ 

- Temporal Lobe,—lying in the middle fossa of the skull, and bounded in front by the fissure of Sylvius.
- Central Lobe, or Island of Reil,—lies in the fissure of Sylvius, covered by the frontal and temporal lobes.
- Limbic Lobe,—arches around the corpus callosum and the hippocampal fissure; is well developed in animals having a keen sense of smell.
- Olfactory Lobe,—situated on the under surface of the frontal lobe, and divided into the olfactory bulb, the olfactory tract, the trigonum, and the posterior olfactory lobule (ant. perforated space).

## Fissures of the Cerebrum are as follows:-

- Longitudinal Fissure,—extends from the front of the cerebrum to the back, separating it into two hemispheres, which are connected in the middle portion by the central commissure, the corpus callosum (10), forming the floor of the fissure in this part of its length.
- Sylvian Fissure, or Fissure of Sylvius,—on each side at the base and lateral side of the brain. Starting at the base in a depression, the vallecula Sylvii, it passes outward to the external surface of the hemisphere, where it divides into a short anterior limb, a short ascending limb, and a horizontal limb. It lodges the middle cerebral artery.
- Fissure of Rolando (1),—on the superior surface of each hemisphere, extending from the longitudinal fissure about its centre, downward and forward toward the fissure of Sylvius, separating the frontal and parietal lobes.
- Parieto-occipital Fissure,—extends from the longitudinal fissure outward for about an inch between the parietal and occipital lobes.
- Calloso-marginal Fissure,—above the gyrus fornicatus on the inner surface of each hemisphere.
- Internal Parieto-occipital Fissure,—extends downward and forward to join the calcarine fissure, on a level with the hinder end of the corpus callosum.
- Calcarine Fissure,—begins close to the posterior extremity of the hemisphere, runs horizontally forward, joined by the parieto-occipital fissure, and terminates a little below the posterior end of the corpus callosum (11).
- Collateral Fissure,—below and external to the preceding, runs forward from the posterior extremity of the brain nearly as far as the tip of the temporal lobe.
- Dentate or Hippocampal Fissure,—commences behind the posterior end of the corpus callosum (11) and runs forward to the recurved part of the hippocampal gyrus.

Transverse Fissure,—a horse-shoe shaped gap or cleft at the base of the brain, extending from the foramen of Munro on each side to the termination of the descending cornu of the lateral ventricle. One-half the fissure is in each hemisphere, and it admits an invagination of the pia mater, which forms the choroid plexus in the lateral ventricle and the velum interpositum in the 3rd ventricle. It gives exit to the venæ Galeni.

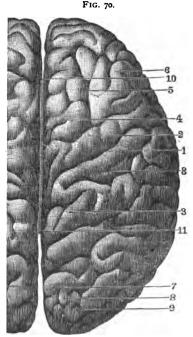

Superior Temporal Sulcus, formerly called the first temporo-sphenoidal fissure,—on the lateral surface of the hemisphere below the fissure of Sylvius.

Cerebral Convolutions. The superior and inner surfaces of each hemisphere are formed of convolutions (gyri) with intervening fissures and depressions (sulci) of various depths, the gyri and sulci being both formed of

gray matter thus arranged to enable it to present a great extent of surface. The convolutions are not uniform in all brains as to arrangement, nor are they symmetrical in the two hemispheres. The principal convolutions are the following-named:—

On the Frontal Lobe are 8,—the ascending (2), superior (4), middle (5) and inferior (6) frontal, externally; the internal, anterior and posterior orbital, inferiorly. The inferior frontal on the left side is named the convolution of Broca and is the language centre.

On the Parietal Lobe are 4,—the ascending (3), superior and inferior parietal, externally; and the quadrate or precuneus, internally. The inferior parietal is subdivided into the supramarginal and the angular gyrus, the latter lying around the posterior end of the superior temporal sulcus (see above).

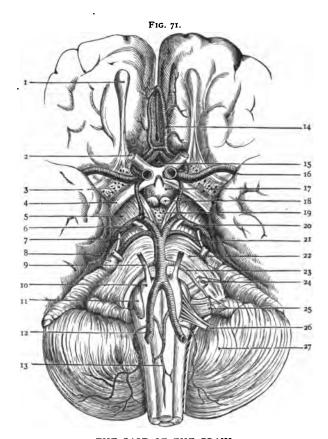

The Occipital Lobe has 4,—the superior (7), middle (8) and inferior (9) occipital, externally; and the cuneate lobule or cuneus, internally.

- The Temporal Lobe has 5,—the superior, middle and inferior temporal, externally; the sub-collateral or 4th temporal, and the sub-calcarine or lingual lobule, inferiorly.
- The Central Lobe or Island of Reil, has 2,—the precentral lobe and the postcentral lobe.
- The Limbic Lobe has 3,—the gyrus fornicatus or callosal convolution, arching from before backward over the corpus callosum; the gyrus hippocampi or hippocampal convolution, having a curved anterior extremity, the uncus; and the dentate convolution, formerly named the dentate fascia.

Under Surface of the Base of the Brain, from before backward, excluding the vessels and the cranial nerves shows the following points for examination. In the middle line are the—

- Longitudinal Fissure,—its anterior portion separating the frontal lobes, and its posterior portion between the occipital lobes
- Corpus Callosum,—the great transverse commissure, seen in the longitudinal fissure, and showing its peduncles, one on each side, to meet the corresponding outer root of the olfactory tract.
- Lamina Cinerea,—a thin, gray layer, continuous with the anterior perforated space, and forming part of the inferior boundary of the 3rd ventricle.
- Optic Commissure,—formed by the junction of the optic tracts.
- Tuber Cinereum (17) —a gray lamina behind the optic commissure, forming part of the floor of the third ventricle. From it projects the—
- Infundibulum,—a hollow process, its canal connecting the pituitary cavity with the 3d ventricle in the fœtus.
- Pituitary Body,—a vascular bi-lobed body, of glandular structure, projects from the infundibulum into the sella turcica of the sphenoid.
- Corpora Albicantia (18),—two round, white eminences, united together; they are the anterior crura of the fornix folded on themselves.
- Posterior Perforated Space (Pons Tarini) (19),—perforated for vessels to the optic thalami; forms part of the floor of the 3rd ventricle.
- Pons Varolii (22),—a broad band of white fibres, passing from one cerebellar hemisphere to the other, (described on page 182).
- Medulla Oblongata (13),—pyramidal in form, emerges from the posterior border of the pons Varolii. (It is described on page 185).
- On each side of the middle line are seen the-
  - Frontal Lobe,—its under surface (see ante, page 171); lying thereon is the—Olfactory Lobe,—consisting of the olfactory bulb (1), the olfactory tract, the trigonum olfactorium, and the posterior olfactory lobule or anterior perforated space (3).

### THE BASE OF THE BRAIN.

1. Olfactory Bulb. 2. Second, or Optic Nerves. 3. Anterior Perforated Space 4. Optic Tract. 5. Crus Cerebri. 6. 3d Nerve. 7. 4th Nerve. 8. 5th Nerve. 9. 6th Nerve. 10. Pyramid. 11. Olivary Body. 12. Vertebral Artery. 13. Anterior Spinal Artery. 14. Anterior Cerebral Artery. 15. Lamina Cinerea. 16. Middle Cerebral Artery. 17. Tuber Cinereum. 18. Corpora Albicantia. 19. Posterior Perforated Space. 20. Posterior Cerebral Artery. 21. Superior Cerebral Artery. 22. Pons Varolii. 23. Inferior Cerebellar Artery. 24. 7th and 8th Nerves. 25. 9th, 10th and 11th Nerves. 26. 12th Nerve. 27. Cerebellum.

Anterior Perforated Space (3) or posterior olfactory lobule,—at the commencement of the fissure of Sylvius; is perforated for small arteries going to the corpus striatum.

Fissure of Sylvius,—is described on page 172.

Optic Tract (4),—runs obliquely across the crus cerebri as a flat band, and enters into the optic commissure.

Crus Cerebri or Cerebral Peduncle (5),—a thick bundle of white matter in front of the anterior border of the pons, passing forward and outward to enter the under surface of the hemisphere. The two crura connect the cerebrum with the cerebellum, medulla oblongata and spinal cord. With the optic tracts they form the boundaries of the inter-peduncular space.

Temporal Lobe,—its inferior surface, (see page 172).

Cerebellum (27),—covering the occipital lobe of the cerebrum. It is described separately, on page 183.

Ventricles of the Brain are 5 in number, of which the two lateral and the 5th belong to the cerebral hemispheres, the 3rd is the cavity of the interbrain, and the 4th belongs to the cerebellum and the medulla oblongata. They are situated as follows:—

Two Lateral Ventricles,—within the substance of the hemispheres, one in each; they are connected with the 3rd ventricle and indirectly with each other by the *joramen of Munro*.

Third Ventricle,—a narrow crevice between the optic thalami, lying below the lateral ventricles and communicating with them by the *joramen of Munro*. It is connected with the 4th ventricle by the *iter a tertio ad quartum ventriculum* or aqueduct of Sylvius.

Fourth Ventricle,—between the cerebellum and the medulla oblongata. Fifth Ventricle,—in the septum lucidum, between the two lateral ventricles.

The Lateral Ventricles are two irregular cavities in the cerebral hemispheres, separated from each other by a partition, the septum lucidum, and each having a central cavity and 3 prolongations or cornua, the anterior in the frontal lobe, the middle in the temporal lobe and the posterior in the occipital lobe. They communicate with each other and with the 3rd ventricle by the foramen of Munro, a Y-shaped opening. The central cavity is situated in the parietal lobe and is bounded as follows:—

Roof,—the under surface of the corpus callosum.

Floor,—from before backward, the caudate nucleus of the corpus striatum, tænia semicircularis, optic thalamus, choroid plexus, one-half of the fornix and its posterior pillar.

Internally,—the septum lucidum, separating it from the opposite ventricle. Externally, in front and behind,—brain-substance.

## Structures named above are briefly described as follows:—

- Corpus Callosum,—the great transverse commissure, arching backward to become continuous with the fornix, reflected below, forming the peduncles at the entrance of the fissure of Sylvius; and marked above by a depression, the Raphé, and longitudinal elevations, the striæ longitudinales or nerves of Lancisi.
- Septum Lucidum,—consists of 2 layers of white and gray matter, lined by epithelium; is placed vertically between the lateral ventricles, from the raphé of the corpus callosum above to the fornix below. The cavity in its centre is the 5th ventricle.
- Fornix,—is a commissure situated beneath the corpus callosum, but continuous with it posteriorly, the septum lucidum separating them in front. It is of triangular form with the apex in front. Its anterior pillars curve downward to the base of the brain, are there reflected, forming the corpora albicantia, and end in the optic thalami. Its posterior pillars pass down the descending horns of the lateral ventricles, along the concavities of the hippocampi majores, and are each continued as the corpus fimbriatum or tania hippocampi, into the uncus or hook of the hippocampal convolution. The Lyra is a series of markings on its under surface.
- Foramen of Munro (foramen commune anterius), -is a Y-shaped opening situated between the anterior pillars of the fornix in front and above and the anterior extremities of the optic thalami below and behind. It is crescentic in outline and by it the lateral ventricles communicate with each other and with the 3rd ventricle.
- Tania Semicircularis,—consists of commissural fibres passing between the corpus striatum and the optic thalamus.
- Choroid Plesses of Veins,—is the margin of a fold of pia mater which enters at the transverse fissure, passes up the descending cornu, through the foramen of Munro, and as the Velum Interpositum spreads out over the roof of the 3d ventricle.

Corpus Striatum,—is described on page 178.

Optic Thalamus,—is described on page 170.

Cornua of the Lateral Ventricles. The Anterior Cornu curves over the anterior end of the corpus striatum into the frontal lobe. The Posterior Cornu curves downward, and inward in the occipital lobe, and contains a smooth eminence, the Hippocampus Minor. The Middle Cornu descends into the temporal lobe to the transverse fissure at the base of the brain, curving backward, outward, downward, forward, and inward, (initials of the Digitized by Google

12

directions form the mnemonic word BODFI). On its floor are the following:—

Hippocampus Major,—a white eminence, about 2 inches long, formed by the infolding of the cerebral cortex to produce the dentate sulcus.

Pes Hippocampi,—the scolloped end of the hippocampus.

Pes Accessorius, or Eminentia Collateralis,—between the hippocampi, at the junction of the middle and posterior cornua.

Corpus Fimbriatum,—a continuation of the posterior pillar of the fornix Choroid Plexus of Veins,—a process of pia mater, (see page 177).

Dentate Convolution (fascia dentata),—a notched band of gray matter, forming part of the limbic lobe.

Transverse Fissure,—at the extremity of the cornu, extending to the foramen of Munro. It is described on page 173.

The Fifth Ventricle is a narrow chink situated between the layers of the septum lucidum, and therefore lies between the lateral ventricles. In the jatus it communicates with the 3rd ventricle by an opening between the pillars of the fornix. Originally it was part of the longitudinal fissure and was shut off by the union of the hemispheres in the formation of the corpus callosum above and the fornix below. It usually contains fluid, of the nature of lymph.

The Corpus Striatum is a body of gray matter imbedded in the white substance of each hemisphere, and is partly seen in the lateral ventricle and its anterior cornu, this part being the—

Nucleus Caudatus (caudate nucleus),—the intra-ventricular portion; a pear-shaped mass, having its narrow end on the outer side of the optic thalamus.

Nucleus Lenticularis (lenticular nucleus),—the extra-ventricular portion, only seen in sections of the hemisphere.

Internal Capsule,—a curved lamina of white matter separating the caudate nucleus from the lenticular posteriorly. It is formed by fibres from the crus cerebri, the corpus striatum and the optic thalamus. Its anterior limb is the portion in front of the curve or genu, its posterior limb lying behind the genu.

External Capsule,—a lamina of white matter bounding the lenticular nucleus externally, and made up of fibres from the anterior commissure and the subthalamic region.

Claustrum,—a thin layer of gray matter on the outer surface of the external capsule, regarded as a detached portion of the gray matter of the island of Reil.

### THE INTER-BRAIN.

The Inter-brain or Thalamen-cephalon, is the region of the 3rd ventricle, and is connected in front and above with the cerebral hemispheres, behind with the mid-brain or mesen-cephalon. Its upper surface is covered by the *fornix*; inferiorly it reaches the base of the brain, forming the structures contained in the *inter-peduncular space*, (see page 176).

The Third Ventricle is a mere fissure, situated between the optic thalami in the median line. It communicates with the lateral ventricles above by the foramen of Munro, and with the 4th ventricle behind by the iter a tertio ad quartum ventriculum. It is crossed by 3 bands, the anterior, middle, and posterior commissures, the middle one being of gray matter, the others of white.

Anterior Commissure,—appears to connect together the corpora striata; its fibres are traced into the temporal lobes, and include fibres from the olfactory tract of the opposite side.

Middle Commissure,—is composed of gray matter and connects the two optic thalami.

Posterior Commissure,—stretches across from one optic thalamus to the other, and contains fibres connecting the two thalami, besides decussating fibres from various parts of the mid-brain.

Boundaries of the Ventricle are as follows:-

Roof,—the velum interpositum, and above it the fornix.

Floor,—the parts comprised in the interpeduncular space at the base of the brain, viz.—the tuber cinereum, with its infundibulum and pituitary body, corpora albicantia, posterior perforated space, and the tegmenta of the crura cerebri.

Anteriorly,—the anterior pillars of the fornix, and the lamina cinerea.

Posteriorly,—the pineal gland, posterior commissure and the iter a tertio ad quartum ventriculum.

Laterally,—the optic thalami and the peduncles of the pineal gland.

The Optic Thalami are two large, oblong masses, composed mainly of gray matter and situated on either side of the 3rd ventricle, between the diverging portions of the corpora striata. Their outer and inferior surfaces are blended with contiguous parts of the brain; their upper, inner and posterior surfaces are free. They are intimately connected, by communicating fibres, with the tegmenta of the crura cerebri, the optic tract, the cerebral cortex, the corpora striata and the corpora albicantia. Each optic thalamus terminates anteriorly and posteriorly in the—

Anterior Tubercle,—the anterior termination, containing the anterior nucleus.

 ${}_{\text{Digitized\_by}}Google$ 

Posterior Tubercle, or Pulvinar,—a rounded prominence, continued into another eminence, the external geniculate body, which is separated from the internal geniculate body of the corpora quadrigemina by one of the roots of the optic tract.

The Pineal Gland, or *Epiphysis Cerebri*, is a small conical, reddish body situated between and upon the anterior corpora quadrigemina (the nates). Its *peduncles* connect with the posterior commissure of the 3rd ventricle and the anterior pillars of the fornix. It consists of a number of follicles, lined by epithelium and containing a viscid fluid and sabulous matter named the—

Acervulus Cerebri,—concretions composed of phosphate and carbonate of lime, phosphate of magnesia and ammonia, with a little animal matter.

## THE MID-BRAIN.

The Mid-brain, or Mesen-cephalon, also called the *Isthmus Cerebri*, is the constricted portion which connects the pons Varolii with the inter-brain and the cerebral hemispheres. Comprised in it are the two crura cerebri on its ventral surface and the four corpora quadrigemina on its dorsal surface, also the corpora geniculata and the aqueduct of Sylvius. In front and above it is continuous with the inter-brain, below with the pons.

The Crura Cerebri, or Peduncles of the Cerebrum, consist of fibres connecting the hemispheres with the medulla oblongata and the spinal cord, called the peduncular fibres. The two crura diverge from each other at the upper margin of the pons, passing forward and outward to enter the hemispheres. Each crus on cross-section shows its fibres arranged in strata, the ventral stratum or crusta and the dorsal stratum or tegmentum.

Crusta,—consists of bundles of white fibre disposed longitudinally in 3 sets, and an oblique bundle named the mesial fillet. The longitudinal fibres are derived from the pyramid of the medulla, and pass through the internal capsule of the corpus striatum upward as the corona radiata to the cerebral cortex.

Tegmentum,—consists of strands of white fibres arranged longitudinally in 4 tracts, one of which is named the fillet. Its fibres pass to the optic thalamus and the subthalamic region, some going directly to the cerebral cortex. Its red nucleus is a tract of gray matter situated on either side of the median line.

Substantia Nigra,—a layer of pigmented gray matter, separating the crusta from the tegmentum.

Corpora Quadrigemina are 4 rounded eminences placed in pairs, 2 in front and 2 behind, on the dorsal surface of the mid-brain, immediately

behind the 3rd ventricle and beneath the posterior border of the corpus callosum. The upper or anterior pair are called the *nates*, the lower pair the *testes*. They are connected by 4 bands, the *brachia*, with the corpora geniculata, those of the nates being continued directly into the optic tract. They are composed of white matter externally and gray matter internally. The anterior pair contain the—

.Stratum Zonale,—a thin stratum of white matter on the surface.

Stratum Cinereum,—next below, a layer of gray matter.

Stratum Opticum,—the upper gray-white layer, having many fine nervefibres intersecting the gray matter.

Stratum Lemnisci,—the deep gray-white layer, consisting of nerve-fibres and nerve-cells of large size.

Corpora Geniculata are two small masses on each side, behind and beneath the posterior end of the optic thalamus. The external one belongs to the optic thalamus (see page 179); the internal one alone being a part of the mid-brain. The former, together with the anterior corpus quadrigeminus and the pulvinar, are intimately connected with vision, constituting the lower cerebral centre for the optic nerve-fibres, which end in them. The internal geniculate bodies are connected with each other by a band of fibres called the commissure of Gudden, and appear to receive some of the fibres of the optic tracts.

Aqueduct of Sylvius, or *Iter a tertio ad quartum ventriculum*, is a narrow canal, about  $\frac{1}{2}$  inch long, connecting the 3rd ventricle with the 4th, and situated between the corpora quadrigemina and the tegmentum. It is surrounded by a layer of gray matter which is continuous with the gray matter of the 3rd and 4th ventricles, and contains groups of cells which are connected with the roots of the 3rd, 4th and 5th cranial nerves.

Other Structures, in close relationship with the parts above described are those mentioned below, the first being again referred to under the Cerebellum. They are the—

Superior Peduncle of the Cerebellum, formerly named the processus e cerebello ad testes,—emerges from the cerebellar hemisphere and runs to the corpus quadrigeminus, passing under it and through the tegmentum to enter the optic thalamus.

Subthalamic Region,—is a forward prolongation of the tegmentum (see ante, page 180), becoming blended with the lower surface of the optic thalamus. It consists of 3 layers named from above downward,—the stratum dorsale, the zona incerta, and the corpus subthalamicum, the latter consisting of gray matter.

## THE HIND-BRAIN.

The Hind-brain, or Epen-cephalon comprises the Pons Varolii, the Cerebellum, and the upper half of the 4th Ventricle. The latter is described with its lower half, under the Medulla Oblongata, in the next section.

The Pons Varolii (6), or Tuber Annulare, is the bond of union of the various parts of the brain, connecting the cerebrum with the cerebellum (3) and the medulla oblongata (9). It is about 1½ inch wide and 1 inch long and thick, and is situated between the hemispheres of the cerebellum above the medulla oblongata and below the crura cerebri. It consists of—a ventral or anterior portion (7), containing 3 layers of fibres, superficial transverse, longitudinal, and deep transverse fibres; also a small quantity of gray matter a tegmental, or dorsal, posterior portion, which is a continuation of the reticular formation of the medulla, most of its constituents being continued into the tegmentum of the crura cerebri. The pons contains the following important collections of nerve-cells:—

Superior Olivary Nucleus,—an isolated mass of gray matter situated on the dorsal surface immediately above the inferior olivary nucleus of the medulla.

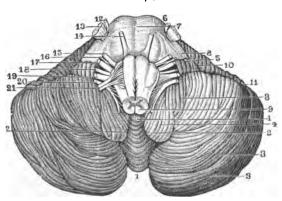

FIG. 72.

Nuclei of the 5th Nerve 2,—one for the motor (12) and one for the sensory root (13), the latter external to the former.

Nucleus of the 6th Nerve,—beneath the floor of the 4th ventricle, close to the root of the facial nerve; its fibres pass through the pons and emerge at its lower margin (14).

Nucleus of the Facial (7th) Nerve,—situated deeply below the floor of the 4th ventricle; its roots follow a tortuous course in the pons, emerging at its lower border (15), external to those of the facial.

Nuclei of the Auditory (8th) Nerve 2,—are dorsal and ventral, both lying chiefly in the medulla but prolonged into the pons; the roots emerging at its lower border (17), in the groove between the olivary and restiform bodies.

Nuclei Pontus,—small masses of gray matter in the ventral or anterior portion of the pons.

The Cerebellum consists of gray matter on the surface and white matter in the interior. Its surface is not convoluted like that of the cerebrum, but is traversed by curved fissures and furrows (sulci), the latter separating the laminæ of which it is composed. It lies in the inferior occipital fossæ of the skull, beneath the occipital lobes of the cerebrum, from which it is separated by a process of dura mater, the tentorium cerebelli. It is divided into a central portion or lobe, the Worm or Vermiform Process (1), and two lateral Hemispheres; all continuous with each other and substantially the same in structure. It presents the following primary fissures:—

Great Longitudinal Fissure (10),—horizontally round the free margin, from the pons in front to the median line behind, giving origin to the secondary fissures.

Incisura Semilunaris, or Anterior Cerebellar Notch,—a broad, shallow, vertical notch, separating the hemispheres in front.

Incisura Marsupialis (2), or Posterior Cerebellar Notch,—a deep notch, separating the hemispheres from each other behind.

Vallecula,—a deep depression on the inferior surface, containing the lower extremity of the worm.

Secondary Fissures of the Cerebellum are 8 in number, 4 superiorly and 4 inferiorly. They pass in a curved direction from side to side across the cerebellum, beginning (except one) and ending in the great longitudinal fissure. They are named from before backward as follows:

On the upper surface of the cerebellum, the-

Pre-central. Post-central. Pre-clival. Post-clival.

On the lower surface of the cerebellum, the-

Post-nodular. Pre-pyramidal. Post-pyramidal. Post-gracile.

The post-gracile is a branch of the post-pyramidal, and ends in the great horizontal fissure.

Lobes of the Cerebellum. The 3 primary lobes, the Worm and the Hemispheres, are divided by the above-named secondary fissures into 19 lobes, named as follows.—

On the upper surface of the Worm, from before backward 5, the— Lingula. Lobulus Centralis. Culmen Monticuli.

Clivus Monticuli. Folium Cacuminis.

On the upper surface of the Hemispheres, from before backward 5, the—
Frænulum. Ala Lobuli Centralis. Anterior Crescentic Lobe.

Posterior Crescentic Lobe. Posterior Superior Lobe.

On the lower surface of the Worm, from before backward 4, the—

Nodule. Uvula. Pyramid. Tuber Valvulæ.

On the lower surface of the Hemispheres, from within outward 5, the—
Flocculus (5). Amygdala (4). Biventral Lobe (3). Slender Lobe (3).

Injerior Semilunar Lobe (3).

White Matter of the Cerebellum includes the peduncular fibres and the fibres proper. The former are arranged in 3 peduncles on each side, which arise from the anterior part of the hemispheres, and connect the cerebellum with itself and with the rest of the brain, as follows:—

Superior Peduncles,—in part form the roof of the 4th ventricle; they pass from the corpus dentatum under the corpora quadrigemina, below which their fibres decussate, going to the red nucleus of the tegmentum, and by a relay through the optic thalamus to the cerebral cortex. Stretching from one peduncle to the other is the—

Valve of Vieussens, or Superior Medullary Velum,—a thin lamina of white matter, which with the superior peduncles forms the roof of the 4th ventricle.

Middle Peduncles (8),—comprise most of the transverse fibres of the pons, and are chiefly commissural fibres connecting the cerebellar hemispheres with each other.

Inferior Peduncles,—connect the cerebellum with the medulla oblongata. Fibræ Propriæ, the proper fibres of the cerebellum,—are of 2 kinds; the commissural, connecting the hemispheres, and the association or arcuate fibres, connecting adjacent laminæ.

Cortical Gray Matter of the Cerebellum is situated on the surface, forming the cortex, a section of which presents a characteristic foliated appearance, named the Arbor Vita, due to the branching of the laminæ given off from the central white matter to the cortical portion. The gray matter of the cortex consists of two layers, as follows:—

Molecular or External Gray Layer,—consists of fibres and cells. At its junction with the granular layer occur the—

Corpuscles of Purkinje,—the characteristic cells of the cerebellum, an incomplete stratum of flask-shaped cells, their bases resting on the granular layer, their necks giving off numerous dendrites to the molecular layer.

Granular or Internal rust-colored Layer,—contains numerous small nervecells or granules of reddish-brown color, also many nerve-fibrils, among which are the axons of the Purkinje corpuscles. This layer also contains larger cells, known as the Golgi cells, situated in its outer part.

Central Gray Matter of the Cerebellum is disposed on each side in 4 centres, one of which, the corpus dentatum, is large; the others being of small size. They are situated in the middle of the white matter of the organ, and are as follows: the—

Corpus Dentatum, or Ganglion of the Cerebellum,—an irregularly-folded lamina of gray matter, having an opening anteriorly, the hilum, from which emerge most of the fibres of the superior peduncle.

Nucleus Emboliformis,—lies to the inner side of the corpus dentatum, partly covering its hilum.

Nucleus Globosus,—an elongated mass on the inner side of the preceding. Nucleus Fastigii, or Roof Nucleus of Stilling,—is close to the middle line at the anterior end of the vermiform process and immediately over the roof of the 4th ventricle.

### THE MEDULLA OBLONGATA.

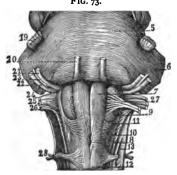

The Medulla Oblongata, or Meten-cephalon, also called the Spinal Bulb, is the lowest division of the brain and is continuous with the spinal cord. It extends from the lower margin of the pons Varolii (5) to a transverse plane (12) corresponding to the lower margin of the foramen magnum. Its ventral surface rests on the basilar groove of the occipital bone, its dorsal surface is in the fossa between the cerebellar hemispheres. It is I inch long, inch broad above, and ½ inch thick; and of pyramidal form, its broad end upward. On its surface are the anterior and posterior median fissures; the former terminating just below the pons in a cul-de-sac, the joramen cacum; the latter expanding into the 4th ventricle about the middle of the medulla. On each side the medulla presents the following parts:—

Pyramid (7),—a bundle of white matter alongside the anterior median fissure, formed by the continuation upward of the direct tract of the anterior column and the crossed tract of the lateral column of the spinal cord. As the latter tract ascends it decussates with its fellow of the opposite side across the fissure, forming the so-called decussation of the pyramids (8).

Olivary Body (9),—an ovoid projection on the outer side of the pyramid and immediately below the pons. In the groove between them the hypoglossal nerve fibres (27) emerge; in that between it and the funiculus of Rolando emerge the glosso-pharyngeal (24), pneumogastric (25)

and spinal accessory (26) nerves. Its nucleus or corpus dentatum is a thin, wavy lamina of gray matter, open at its upper and inner part.

Fig. 73.

Two accessory nuclei are also situated in its substance.

Funiculus of Rolando (10),—a slight, longitudinal prominence on the outer side of the olivary body. It corresponds to a mass of gray matter, substantia gelatinosa, continuous with the posterior horn of the gray matter of the cord.

Lateral Column,—hidden above by the olivary body but showing below it; is the continuation of the lateral column of the cord in part.

Restiform Body,—between the lateral column and the funiculus cuneatus;

contains the arcuate fibres, external and internal, and the direct cerebellar tract. The two restiform bodies diverge as they ascend, assist in forming the lateral walls of the 4th ventricle, and enter the cerebellar hemispheres as the inferior peduncles of the cerebellum.

Funiculus Cuneatus,—between the restiform body and the funiculus gracilis; is the continuation of the postero-lateral column of the cord.

Funiculus Gracilis (posterior pyramid)—a narrow, white band, parallel to and alongside the posterior fissure; is the continuation of the posteromedian column of the cord. Its enlarged upper extremity is clubshaped and called the clava.

Other Structures in the Medulla. Internally the medulla is composed of longitudinal bundles of nerve-fibres, masses of gray matter constituting nerve nuclei, and nerve-fibres originating from the nuclei. The—

Independent Nuclei,—are those of the 5th, 8th, 9th, 10th, 11th and 12th cranial nerves, which arise in or near the floor of the 4th ventricle; also the nucleus of the funiculus teres, that of the olivary body, the accessory olivary nuclei, and the funiculus solitarius, the ascending root of the 9th nerve

Raphé or Median Septum,—is situated in the middle line of the medulla above the decussation of the pyramids, and consists of fibres having different directions and of multipolar nerve-cells.

Formatio Reticularis,—is a coarse net-work, situated within the anterior and lateral regions of the medulla, and is formed by the breaking up of the anterior gray matter by the white fibres of the crossed pyramidal tracts.

The Fourth Ventricle, or Ventricle of the Cerebellum, is a diamond-shaped cavity lying between the cerebellum and the posterior surface of the pons Varolii and medulla oblongata. Its upper angle corresponds with the lower opening of the aqueduct of Sylvius, by which this ventricle communicates with the 3rd ventricle. Its lower angle is continuous with the central canal of the spinal cord, and is called the calamus scriptorius, from its resemblance to the point of a pen. The ventricle is closed posteriorly by a layer of pia mater, the tela choroidea injerior, with its choroid plexuses, in which layer are 3 openings; the foramen of Magendie, just above the calamus scriptorius in the median line, and the foramina of Key and Retzius at the extremities of the lateral angles. Through these foramina the ventricles of the brain communicate with the subarachnoid space of the brain and spinal cord. The fourth ventricle is bounded as follows:—

Roof,—is tent-shaped and formed by the superior peduncles of the cerebellum, the valve of Vieussens, the tela choroidea inferior (see above) and its choroid plexuses, the obex, and the inferior medullary velum.

Floor,—is formed by the posterior surface of the pons above and the medulla below. It contains the median furrow, on each side of which are—the fasciculus teres, striæ acusticæ, conductor sonorus, fovea superior, fovea inferior, ala cinerea, tuberculum acusticum, locus cæruleus, tænia violacea, and the eminences of origin of certain nerves (see below).

Laterally,—in the upper part are the superior peduncles of the cerebellum; in the lower part, the inferior peduncles (restiform bodies) fringed by the funiculi graciles, their clavæ and the ligulæ.

# Parts named above, and heretofore undescribed, are the-

Sulcus Longitudinalis Medianus,—the vertical median fissure; from the centre of which on each side emerge the—

Striæ Medullaris or Striæ Acusticæ—white fibres crossing the floor of the ventricle transversely, dividing it into two triangles, and passing outward to the auditory nerve. They are the axons of the nerve-cells of the tuberculum acusticum.

Conductor Sonorus,—a whitish band of fibres, connected on each side below and internally with the striæ medullaris.

Inferior Medullary Velum,—a thin layer of white matter, stretching over the ventricle toward its lateral angles.

Obex and Ligula,—are respectively the inferior and superior parts of a little irregular ridge, which runs from the clava of the funiculus gracilis to its fellow of the opposite side.

Eminentia Teres,—the prominent centre of a spindle-shaped eminence

made by an underlying bundle of white fibres, the *funiculus teres*, formed in part by the fibres of the facial nerve.

Fovea Superior,—an angular depression, external to the fasciculus teres and above the striæ medullaris.

Locus Caruleus,—a bluish depressed area above the fovea superior.

Fovea Inferior,—an angular groove, its apex at the striæ, its limbs diverging below, enclosing the—

Ala Cinerea or Trigonum Vagi,—a triangular area, corresponding with the nuclei of the vagus and glosso-pharyngeal nerves.

Eminentia Cinerea,—a prominent elevation of the ala cinerea.

Trigonum Hypoglossi,—a triangular area, internal to the inner limb of the fovea inferior, and corresponding to the tract of nerve-cells from which the hypoglossal nerve originates.

Trigonum Acustici,—a triangular area, external to the outer side of the fovea inferior, having at its base a prominence, the tuberculum acusticum.

Nuclei of Origin, in the floor of the 4th Ventricle, comprise the nuclei of the cranial nerves from the 5th to the 12th inclusive, also vaso-motor, cardiac and respiratory centres. Near the ventricle, in the anterior wall of the aqueduct of Sylvius, are the nuclei for the 3rd and 4th nerves. Those in the floor itself are as follows:—

- 5th Nerve (trigeminus),—two groups of cells, extending the length of the medulla and alongside the aqueduct of Sylvius, the nuclei lying close to the lateral recesses of the ventricle
- 6th Nerve (abducens),—in the upper part, close to the median line.
- 7th Nerve (facial),—below and external to the 6th.
- 8th Nerve (auditory), 2 nuclei, one beneath the striæ, the other just outside the ventricle.
- 9th Nerve (glosso-pharyngeal) and 10th Nerve (vagus),—in the upper part of the ala cinerea, near the inferior angle of the ventricle.
- 11th Nerve (spinal accessory),—below the preceding, in the lower part of the ala cinerea, and running down into the cord as low as the 6th cervical vertebra.
- 12th Nerve (hypoglossal),—internal to the 9th and 10th, beneath the fasciculus teres, and in the trigonum hypoglossi.

### THE SPINAL CORD.

The Spinal Cord is that part of the cerebro-spinal axis which is situated in the spinal canal. Its length is about 17 or 18 inches, terminating at the lower border of the 1st lumbar vertebra in the *filum terminale* (16). It is cylindrical in general form, with 2 enlargements, one in the cervical region, the other in

the lumbar. It is composed of gray and white matter, the gray being inside (instead of outside, as in the cerebrum), and arranged so as to present a crescentic appearance in horizontal section, joined by a transverse commissure, and the extremities forming the Anterior and Posterior Horns, from

which regions respectively the anterior and posterior roots of the spinal nerves have their apparent origin.

The-

Membranes—of the cord are 3, as in the brain: the dura mater, arachnoid, and pia mater. The Dura Mater represents only the meningeal or supporting layer of the cranial dura mater. It is not adherent to the spinal column, but is connected thereto by fibrous tissue. The Arachnoid is arranged as on the brain, its sub-arachnoid space being filled with its fluid, for the protection of the cord. The Pia Mater has a fibrous band on each side, the ligamentum denticulatum (9), connecting it to the dura mater by 21 serrations.

Fissures,—number 8, the anterior and posterior median, the postero-lateral (11) and the posterior intermediate on each side.

Columns,—are 4 in number, 2 on each side of the cord; a small posterior column, and a large antero-lateral column, separated from each other by the postero-lateral fissure. The posterior column is further divided in its upper part, into a postero-median and a postero-lateral column, which are separated from each other by the posterior intermediate septum.

Central Canal,—a minute canal, barely visible to the naked eye, extends the whole length of the cord, originating above in the lower

angle of the 4th ventricle (1) and terminating below in a somewhat dilated extremity.

FIG. 74.

White Substance of the Cord consists of medullated fibres, mostly disposed longitudinally, but some obliquely and transversely, also blood-vessels and neuroglia. The Neuroglia supports the fibres and cells of the gray substance as well as the fibres of the white, and is accumulated in three situations: on the surface of the cord, beneath the pia mater; around the central

canal, as the substantia gelatinosa centralis; as a cap over the posterior horn of gray matter, forming the substantia cinerea gelatinosa.

Nerve-tracts in the white substance of the cord, shown by investigation of pathological lesions, as extending along various portions of the cord and into or from the brain, are 8 in number, as follows:—

In the antero-lateral column are 6, the-

Direct Pyramidal Tract,—next to the median fissure and in the upper part of the cord; consists of descending fibres from the motor area of the cerebral cortex of the same side, passing through the pyramid of the medulla, crossing in the anterior white commissure of the cord, and disappearing about the middle of its dorsal region.

Crossed Pyramidal Tract,—in the hinder part of the column; consists of descending fibres from the motor area of the cortex on the opposite side, through the pyramid of the medulla, crossing in the decussation of the pyramids.

Antero-lateral Ascending (Gower's) Tract,—in the anterior part of the column; consists of ascending fibres arising from cells in the posterior horn, crossing in the anterior gray commissure, and passing upward through the medulla and pons to the cerebellum through its superior peduncles.

Direct Cerebellar Tract,—behind the preceding, commencing in the lumbar region; consists of fibres from cells in the posterior gray matter, ascending through the restiform body to the cerebellum.

Tract of Lissauer — a small tract, formed by some of the fibres of the posterior roots of the spinal nerves, running upward for a short distance and entering the posterior horn of gray matter.

Antero-lateral Ground Bundle,—is the remaining part of the column, situated next to the gray matter of the cord; contains—longitudinal commissural fibres, uniting cell-groups of the gray matter with each other; fibres crossing the anterior commissure from the gray matter of the opposite side; horizontal fibres belonging to the anterior roots of the spinal nerves.

In the Posterior Column are 2 tracts, the-

Tract of Goll,—next to the posterior fissure; consists of fibres from the posterior roots of the spinal nerves, ascending to the medulla where they end in the nucleus gracilis.

Tract of Burdach,—between the preceding and the gray matter; consists of fibres from the posterior roots of the spinal nerves, some ascending a short distance and entering the gray matter, others entering Goll's tract and passing to the medulla.

Gray Substance of the Cord occupies the central portion, a transverse

section showing it in the form of two crescents joined by the gray commissure. Each crescent has an anterior and a posterior cornu or horn; a lateral horn being also seen in the upper dorsal region. The gray substance consists of nerve-fibres, nervecells, blood-vessels and connective tissue. The—

Nerve-fibres,—are found as a dense interlacement of minute fibrils, formed of the axons and dendrons of the nerve-cells and nerves of larger size.

Nerve-cells,—some form columns of cells placed longitudinally, and some are scattered throughout the gray matter.

Clarke's Posterior Vesicular Column,—is a group of nerve-cells at the base of the posterior horn on its inner side, extending from the 8th cervical nerve to the 2nd lumbar.

The Spinal Nerves are transmitted from each side of the spinal cord through the intervertebral foramina of the spinal column, in 31 pairs, of which the cervical number 8, the dorsal 12, the lumbar 5, the sacral 5, and the coccygeal 1. Each nerve arises by two roots; an anterior (13) or motor root, and a posterior (10) or sensory root, the latter being distinguished by a ganglion, the spinal ganglion (12). These nerves are described separately infra, after the description of the cranial nerves. The—

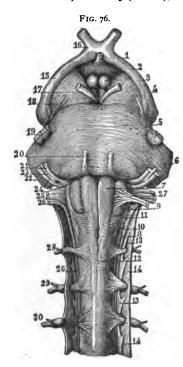

Cauda Equina (17) (horse's tail),—is a sheaf of nerves composed of the elongated roots of the 4 upper sacral nerves, passing downward to reach their respective foramina of exit from the spinal canal.

### THE CRANIAL NERVES.

The Cranial Nerves number 12 pairs (9 according to Willis); those from the 5th to the 12th inclusive having their deep origin wholly or in part from the floor of the 4th ventricle, and all, except the first two, originating in or near that situation. Their superficial or apparent origin is their connection with the surface of the brain, their deep or real origin lies in some special nucleus of gray matter deeply situated in the brain. After emerging from the surface

the nerves pass through tubular prolongations of the dura mater in various foramina at the base of the skull, to their final distribution.

1st Nerve, Olfactory (Plate 6), nerves of smell, about 20 in number, com-

posed of non-medullated fibres,—arise from the under surface of the olfactory bulb (see page 174); deeply by 2 white roots from the limbic lobe, and by the middle gray root (trigonum olfactorium) from the optic thalamus; exit by numerous foramina in the cribriform plate of the ethmoid bone; to form a plexiform network over the upper third of the nasal septum, the superior turbinated bone and the adjacent surface of the ethmoid bone, from which branches are distributed to the Schneiderian membrane of the nose.

2nd Nerve, Optic, nerve of sight (Plate 6),—arises from the optic commissure (16) and tracts (15); deeply from the external geniculate body, the pulvinar of the optic thalamus, and the upper quadrigeminal body, these being the lower visual centres; also from the cuneus and probably the lingual lobule of the occipital lobe (cortical visual centres); exit by the optic foramen; to the retina of the eye. [This nerve and the optic tract

are more fully described under the sub-title Nerves of the Eye.]

3rd Nerve, Motor Oculi, (Plate 6), motor nerve of the eye-ball,—arises from the inner side of the crus cerebri (17), in front of the pons (5); deeply from a nucleus in the floor of the aqueduct of Sylvius; exit by the sphenoidal fissure; to all the muscles of the orbit except the superior oblique and external rectus, also through the ciliary ganglion to the sphincter of the iris and the ciliary muscle.

4th Nerve, Trochlear or Pathetic, (Plate 6) motor of the eye-ball,—arises from the outer side of the crus cerebri (18), in front of the pons; deeply

from a nucleus in the floor of the aqueduct of Sylvius, below that of the 3rd nerve; exit by the sphenoidal fissure; to the superior oblique muscle of the eve-ball, and by a recurrent branch

to the wall of the lateral sinus.

5th Nerve, Trifacial or Trigeminus (Plate 7), nerve of sensation and motion,—arises by 2 roots (10) from the side of the pons Varolii: deeply from a nerve-tract in the medulla oblongata and the locus cæruleus (sensory root), the floor of the 4th ventricle and the wall of the aqueduct of Sylvius (motor root); exit in 3 divisions by the sphenoidal fissure, the fora men rotundum and the foramen ovale respectively. The Gasserian ganglion (5) is situated on its sensory root at the origin of the three divisions. This nerve resembles a spinal nerve in arising by two roots, in having a ganglion on its posterior (sensory) root, and in its

compound function. It is the great sensory nerve of the head and face, and the motor nerve of the muscles of mastication. Its divisions are the ophthalmic, the superior maxillary and the inferior maxillary, as follows:-

OPHTHALMIC (6), a sensory nerve,—exit by the sphenoidal fissure; to the eye-ball, lachrymal gland, mucous lining of the eye and nasal fossæ, and the skin of the forehead, eyebrow and nose. Its branches are the-

Frontal (9) { Supra-orbital. Supra-trochlear. Lachrymal (10) { Branches to the gland, the conjunctiva, and the eyelid.

Ganglionic, to the ciliary ganglion.

Ciliary, to the ciliary muscles, iris and cornea.

Infra-trochlear, to the skin of the eyelids and side of the nose, the conjunctiva, lachrymal sac and caruncula lachrymalis.

SUPERIOR MAXILLARY (7), a sensory nerve,—exit by the foramen rotun-Digitized by Google

dum; to the temple, cheek, lower eyelid, nose, lip, upper teeth and the spheno-palatine ganglion, thence to the palate. Its branches are the—

Meningeal.	Posterior Sup. Dental (16).	•	Palpebral.
Orbital (20) $\left\{ \begin{array}{l} \text{Temporal.} \\ \text{Malar.} \end{array} \right.$	Middle Superior Dental.		Nasal.
Malar.	Anterior Sup. Dental (18).		Labial.
Spheno-palatine.			

INFERIOR MAXILLARY (8), includes the motor root of the 5th, and is a nerve of motion, common sensation and special sense (taste). Its exit is by the foramen ovale. Its recurrent branch goes to the dura mater and the lining of the mastoid cells; its motor filaments to the muscles of mastication; its sensory ones to the teeth and gums of the lower jaw, the skin of the temple and external ear, the lower face and lip, and the anterior 3rds of the tongue. Its branches are the—

Recurrent.  Internal Pterygoid.  Masseteric.  Deep Temporal (2).  Buccal.  External Pterygoid.  Auriculotemporal (26)	Br. to the facial nerve. Br. to otic ganglion. Ant. Auricular 2. Brs. to meatus auditorius 2. Articular. Parotid. Superior Temporal.
---	--

Lingual or Gustatory (23),—to the tongue, mouth, gums and sublingual gland: communicates with the facial, inferior dental and hypoglossal nerves and the sub-maxillary ganglion.

Inferior Dental (24) 

Mylo-hyoid (28), to that muscle and digastric.

Dental Brs. to the molar and bicuspid teeth.

Incisive, to the canine and incisor teeth.

Mental (25), to the chin and lower lip.

6th Nerve, Abducent, (Plate 10), motor of the eye-ball,—arises from the pyramid of the medulla oblongata, close to the pons (20 Fig. 76); deeply from the floor of the 4th ventricle, beneath the eminentia teres; exit by the sphenoidal fissure; to the external rectus muscle of the eyeball.

7th Nerve, Facial, Portio Dura, (Plate 8), is the motor nerve of the face, the stapedius, the muscles of the external ear and other muscles; while its chorda tympani branch is the nerve of taste for the anterior 3rds of the tongue, and the vaso-dilator of the sub-maxillary and sub-lingual glands. It arises from the upper part of the medulla oblongata, in the groove between the olivary and restiform bodies (21 Fig. 76); deeply in the floor of the 4th ventricle, from a nucleus in the lower part of the pons near that of the 6th nerve; exit by the internal auditory meatus, through the aquæductus Fallopii and

the stylo-mastoid foramen; to the muscles of expression of the face, those of the ear, etc., and to the tongue. Behind the ramus of the jaw its diverging branches form the pes anserinus or goose's foot. It communicates, with the meningeal sympathetic plexus by the external superficial petrosal nerve; with the spheno-palatine and otic ganglia, by the large and small superficial petrosal nerves; with the auditory, great auricular, auriculo-temporal, pneumogastric, glosso-pharyngeal, small occipital, and superficial cervical nerves, the three divisions of the 5th nerve, and the carotid plexus. The petrosal nerves mentioned above are given off by the geniculate ganglion, a swelling on the 7th nerve in the aquæductus Fallopii (described separately). Its branches of distribution are the—

Tympanic,—to the stapedius muscle.

Chorda Tympani,—nerve of taste, etc. (see above).

Posterior Auricular,—dividing into Auricular and Occipital.

Digastric,—to that muscle.

Stylo-hyoid,—to that muscle.

Temporo-jacial

Temporo-jacial

Temporo-jacial

Temporo-jacial

Malar Brs. to the occip.-frontalis and the lower eyelid.

Infra-orbital { Superficial Brs.
 Deep Brs.

Buccal Brs. to the mouth and cheek muscles.

Supra-maxillary or Mandibular Brs.

Infra-maxillary or Cervical Brs.

8th Nerve, Auditory, Portio Mollis (Plate 10), the special nerve of the sense of hearing, is soft in texture and destitute of neurilemma,—arises from the groove between the pons and medulla, between the restiform body and the 7th nerve (22 Fig. 76); deeply from the floor of the 4th ventricle by 2 roots, one from the trigonum acustici, the other from the accessory nucleus and the tuberculum acusticum. Goes by the internal auditory meatus; to the internal ear. It is the only cranial nerve which does not leave the cranium. Its branches are two, the—

Vestibular, to the vestibule. Cochlear, to the cochlea.

[This nerve is more fully described under the Internal Ear.]

oth Nerve, Glosso-pharyngeal, (Plate 9), sensory nerve and nerve of taste,—arises by 3 or 4 filaments from the medulla oblongata in the groove between the olivary and restiform bodies (24 Fig. 76); deeply from a nucleus in the floor of the 4th ventricle and the funiculus solitarius in the lower part of the medulla; exit by the jugular foramen; to the mucous membrane of the fauces and base of the tongue, and the mucous glands of the mouth and

tonsil. It communicates with the facial, pneumegastric and sympathetic nerves. Its branches of distribution are the—

Tympanic or Jacobson's Nerve,—described under the Ear.

Carotid Branches,-along the internal carotid artery.

Pharyngeal,—to the pharyngeal plexus.

Muscular,—to the stylo-pharyngeus muscle.

Tonsillar Branches,—forming the tonsillar plexus, thence to the soft palate and fauces.

Lingual 2,—one to the base, the other to the posterior half of the tongue, being distributed to the mucous membrane, the papillæ and the follicular glands.

roth Nerve, Pneumogastric or Vagus, (Plate 9),—the auriculo-laryngo-pharyngo-esophago-tracheo-pulmono-cardio-gastro-hepatic nerve, (Pancoast), is composed of both motor and sensory fibres. It arises by 8 or 10 filaments from the medulla oblongata (25 Fig. 76), between the olivary and restiform bodies; deeply from the nucleus vagi in the floor of the 4th ventricle, the funiculus solitarius and the nucleus ambiguus in the medulla; exit by the jugular foramen; and is distributed to the parts and organs named in the above euphonious appellation; supplying sensory and motor fibres to the organs of voice and respiration, and motor fibres alone to the pharynx, esophagus, stomach and heart. It has a ganglion on its root and another on its trunk, thereby communicating with the 7th, 9th, 11th and 12th cranial nerves, the 1st and 2nd cervical nerves and the sympathetic. Its branches of distribution are the—

Meningeal,—a recurrent filament to the dura mater.

Auricular or Arnold's Nerve,-to the external ear.

Pharyngeal,—to the pharyngeal plexus.

Superior Laryngeal,—a nerve of sensation to the larynx, dividing into the External and Internal Laryngeal.

Recurrent Laryngeal,—the motor nerve of the larynx; gives off œsophageal, tracheal and pharyngeal branches.

Cervical Cardiac Branches,—to the cardiac plexuses.

Thoracic Cardiac Branches,—to the déep cardiac plexus.

Anterior Pulmonary Branches,-to that plexus.

Posterior Pulmonary Branches,-to that plexus.

Esophageal Branches,—to the œsophageal plexus.

Gastric,—on the left side of the body to the anterior surface of the stomach, on the right side to the posterior surface; some filaments going to the hepatic plexus.

11th Nerve, Spinal Accessory, (Plate 9), a motor nerve; consists of

two parts, the accessory to the vagus and the spinal portion. The Accessory portion arises by 4 or 5 filaments from the medulla below the vagus (26 Fig. 76); deeply from a nucleus near the floor of the 4th ventricle; exit by the jugular foramen; to the pharyngeal and superior laryngeal branches of the vagus and through the former probably supplying the muscles of the soft palate. The Spinal portion arises by several filaments from the lateral tract of the cord as low as the 6th cervical nerve; deeply from the intermedio-lateral gray tract of the cord; exit by the jugular foramen, having first entered the skull by the foramen magnum; to the sterno-mastoid and trapezius muscles, forming plexuses with the 2nd, 3rd and 4th cervical nerves.

notor nerve of the tongue,—arises by 10 to 15 filaments from the medulla oblongata in the groove between the pyramid and the olivary body (27 Fig. 76); deeply from the trigonum hypoglossi in the floor of the 4th ventricle; exit by the anterior condyloid foramen in two bundles; to certain muscles of the tongue and other muscles; communicating with the vagus, sympathetic, 1st and 2nd cervical and the lingual. Its branches of distribution are the—

Meningeal Branches,—to the dura mater.

Descendens Hypoglossi,—to the sterno-hyoid, sterno-thyroid and omohyoid muscles; joins the communicans hypoglossi branch of the cervical plexus.

Thyro-hyoid,—to the thyro-hyoid muscle.

Muscular Branches,—to the stylo-glossus, hyo-glossus, genio-hyoid and genio-hyo-glossus muscles, and to the intrinsic muscles of the tongue.

Nerves entering the Cranium before passing out of it, are the spinal portion of the spinal Accessory, and the Nasal branch of the Ophthalmic division of the 5th nerve. The first enters by the foramen magnum, and leaves by the jugular foramen. The second enters from the orbit by the anterior ethmoidal foramen, and leaves by the nasal slit at the side of the crista galli.

#### GANGLIA OF THE CRANIAL NERVES.

Ganglia are on and connected with several of the cranial nerves. Those connected with the 5th nerve have each motor, sensory and sympathetic roots. The various ganglia are named and connected as follows:—

With the 3rd Nerve,—the ophthalmic ganglion.

On the Fifth Nerve,—the Gasserian or semilunar ganglion.

With the 5th Nerve,—the ophthalmic, the spheno-palatine (Meckel's), the otic, and the submaxillary ganglia.

On the 7th Nerve,—the geniculate ganglion or intumescentia ganglioformis.

With the 7th Nerve,—the spheno-palatine (Meckel's) ganglion, and the otic ganglion.

On the 9th Nerve,—the jugular and petrous ganglia.

On the 10th Nerve,—the jugular or ganglion of the root, and the inferior or ganglion of the trunk.

With the 11th Nerve,—the jugular ganglion of the 10th nerve is connected with the accessory portion of the 11th.

Gasserian or Semilunar Ganglion, (Plate 7), on the sensory root of the 5th nerve, is situated near the apex of the petrous portion of the temporal bone. It communicates with the carotid plexus of the sympathetic by filaments on its inner side. Its branches are the 3 divisions of the 5th nerve, the ophthalmic, superior maxillary, and inferior maxillary, the latter trunk being joined by the motor root of the nerve outside the cranium. The ganglion also gives off minute branches to the tentorium cerebelli and the dura mater in the middle cranial fossa.

Ophthalmic, Ciliary or Lenticular Ganglion (Plate 6), is about the size of a pin's head, and is situated at the back of the orbit. Its roots are 3 in number,—a sensory, from the nasal branch of the ophthalmic; a motor, from the 3rd nerve; and a sympathetic root, from the cavernous plexus. Its branches are the short ciliary nerves, to the ciliary muscle, the iris and the cornea.

Spheno-palatine or Meckel's Ganglion (Plate 7), the largest of the cranial ganglia, is situated in the spheno-maxillary fossa, close to the spheno-palatine foramen. Its roots are—a sensory, from the superior maxillary nerve; a motor, from the facial, through the large superficial petrosal; and a sympathetic root, from the carotid plexus, through the large deep petrosal; the two last-named joining to form the Vidian nerve before entering the ganglion. Its branches are the—

Ascending Branches,—to the orbit.

Anterior or Large Palatine,—to the gums and hard palate.

Middle or External Palatine,—to the uvula, tonsil and soft palate.

Posterior or Small Palatine,—to the levator palati and azygos uvulæ muscles. the soft palate, tonsil and uvula

Superior Nasal Branches,—to the mucous membrane of the superior and middle turbinated bones, and that lining the posterior ethmoidal cells.

Naso-palatine,—to the mucous membrane behind the incisor teeth, and that of the septum of the nose.

Pharyngeal or Pterygo-palatine.—to the mucous membrane of the upper part of the pharynx

Upper Posterior Nasal Branches,—to the mucous membrane at the back of the roof of the mouth, and that of the septum and superior meatus of the nose.

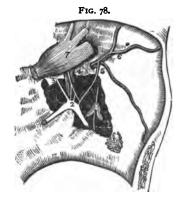

Otic Ganglion, Arnold's, (Plate 7), is situated on the inner surface of the inferior maxillary nerve, immediately below the foramen ovale. Its roots are—a sensory, from probably the glosso-pharyngeal; a motor, from probably the facial; both through the small superficial petrosal continued from the tympanic plexus; and a sympathetic root from the middle meningeal plexus. It communicates also with the internal pterygoid branch of the inferior maxillary, and with the auriculo-temporal. Its branches are—a filament to the tensor tympani muscle, one to the tensor palati, and one to the chorda tympani nerve.

Sub-maxillary Ganglion (Plate 7) is situated above the sub-maxillary gland. Its roots are—a sensory, from the lingual branch of the inferior maxillary; a motor, from the facial by the chorda tympani; and a sympathetic root from the facial plexus. Its branches are 5 or 6 in number, distributed to the mucous membrane of the mouth, Wharton's duct, and the sub-maxillary gland.

Geniculate Ganglion (2) or Intumescentia Ganglioformis, (Plate 8), is a

reddish, gangliform swelling on the 7th or facial nerve, situated in the aquæductus Fallopii, behind the tympanum and near the Gasserian ganglion. It communicates with the spheno-palatine ganglion, the otic ganglion and the meningeal plexus of the sympathetic, by the 3 superficial petrosal nerves, which are seen on removing the Gasserian ganglion (7), as follows:—

Large Superficial Petrosal (3),—
passes through the hiatus Fallopii,
thence through the foramen lacerum medium to the Vidian canal
where it joins the large deep petrosal from the carotid plexus,

to form the Vidian nerve, as which it goes to Meckel's ganglion (page 198), forming its motor root.

Small Superficial Petrosal (4),—immediately external to the preceding, going from the geniculate ganglion of the 7th to the otic ganglion, lying directly over the tensor tympani muscle.

External Superficial Petrosal (5),—going from the 7th nerve to the sympathetic plexus on the middle meningeal artery (6).

The Vidian Nerve (Plate 8), is a short nerve of communication, between the facial and sympathetic on the one hand, and the spheno-palatine ganglion on the other, supplying that ganglion with its motor and vaso-motor roots. It is formed by the junction of the—

Large Superficial Petrosal, br. of the facial (p. 194), with the-

Large Deep Petrosal, br. of the carotid plexus (p. 208), which occurs in the cartilage filling in the foramen lacerum medium (p. 45). It then enters the Vidian canal (p. 30) in the pterygoid process of the sphenoid bone, passing through which it finally joins the posterior part of the sphenopalatine ganglion (p. 198). Some filaments, the—

Upper Posterior Nasal Branches,—are apparently given off from the Vidian in the canal, to the septum and roof of the nose; but they are really branches from the ganglion, bound up in the same sheath with the Vidian nerve (see page 199).

Ganglia of the 9th Nerve (Plate 9). The Jugular Ganglion is regarded as a segmentation from the petrous ganglion below. The Petrous Ganglion is situated in a depression on the lower border of the petrous portion of the temporal bone. From it arise the filaments which connect the 9th nerve with the 10th and the sympathetic; and it communicates also with the 7th nerve. Its branches of distribution are the tympanic, carotid, pharyngeal, muscular, tonsillar, and lingual branches of the 9th nerve (see page 196.)

Ganglia of the 10th Nerve (Plate 9). The Ganglion of the Root is connected by filaments with the accessory portion of the 11th nerve, with the petrous ganglion of the 9th, with the 7th, and with the sympathetic. The Ganglion of the Trunk involves all the fibres of the nerve, as also the accessory portion of the 11th, which passes through it. It is connected with the 12th nerve, the superior cervical ganglion of the sympathetic, and the loop between the 1st and 2nd cervical nerves.

## THE SPINAL NERVES.

The Spinal Nerves number 31 pairs, of which the cervical number 8, the dorsal 12, the lumbar 5, the sacral 5, and the coccygeal 1. The 1st cervical escapes above the 1st vertebra, each of the others below the corresponding vertebra through the intervertebral foramina. Each nerve arises by 2 roots,

-an anterior motor root, and a posterior sensory one, the latter having a ganglion on it, the spinal ganglion, situated in the intervertebral foramen. The roots unite, and the spinal nerve thus formed divides into 2 divisions, both having motor and sensory fibres. The posterior divisions are small and generally unimportant; they supply the muscles and integument of the back. The anterior divisions supply the neck, front, and sides of the trunk, and the extremities; uniting in various regions to form plexuses, from which important nerve-trunks originate. Each anterior division is connected by a slender filament with the sympathetic.

### THE CERVICAL NERVES.

The Cervical Nerves, (Plate 11), are 8 in number. The anterior divisions of the 4 upper form the cervical plexus; the anterior divisions of the 4 lower, together with the 1st dorsal, form the brachial plexus. The posterior division of the 1st cervical, the suboccipital nerve, differs from the others in not dividing into internal and external branches.

The Cervical Plexus, (Plate 11), is formed by the anterior divisions of the 4 upper cervical nerves. It is situated opposite the four upper cervical vertebræ, resting on the levator anguli scapulæ and scalenus medius muscles and covered in by the sterno-mastoid. Its branches number 10, of which the first 4 are superficial and the last 6 are deep, as follows:

Occipitalis Minor,—ascending to the back of the side of the head.

Auricularis Magnus, { Facial, to the skin over the parotid gland. Auricular, to the skin of the pinna, concha, etc. Mastoid, to the integument behind the ear.

Superficialis Colli,—by 2 branches to the skin of the neck.

Supraclavicular,

Supraclavicular,—to the skin of that region.

Supraclavicular,—to the skin over the pectoral and deltoid.

Supra-acromial,—to the skin of the shoulder.

Communicating.—brs. to the 10th, 12th and sympathetic nerves.

Muscular,—to the anterior recti and rectus lateralis muscles.

Communicantes Hypoglossi 2, join the descendens hypoglossi nerve.

Phrenic,—is described below.

Deep Communicating,—to the spinal accessory nerve.

Deep Muscular,—to the sterno-mastoid, trapezius, levator anguli scapulæ and scalenus medius muscles.

The Phrenic Nerve, or Internal Respiratory of Bell, arises by 3 heads from the 3d, 4th, and 5th cervical, descends across the front of the scalenus anticus, crossing the subclavian and internal mammary arteries in the middle mediastinum, and is distributed to the inferior surface of the diaphragm. It sends filaments to the pericardium and pleura, and communicates with the solar and phrenic plexuses of the sympathetic in the abdomen. On the right side of the body it is situated more deeply, and is shorter and more vertical in direction than on the left side. In the thorax each phrenic nerve is accompanied by the comes nervi phrenici artery, a branch of the internal mammary.

The Brachial Plexus, (Plate 12), is formed by the union of the anterior division of the four lower cervical nerves and the first dorsal. The 5th, 6th and 7th cervical unite into one trunk externally to the scalenus medius, as also do the 8th cervical and 1st dorsal behind the same muscle. Below the line of the clavicle both these trunks bifurcate; the two adjacent branches unite behind the axillary artery making the Posterior Cord, and the remaining 2 form the Outer and Inner Cords, referred to the artery. Each of these cords bifurcates, but the 2 adjacent branches of the outer and inner cords unite over the artery, to form the Median Nerve, leaving 4 other branches,—the Ulnar, derived from the inner cord, the Musculo-cutaneous, from the outer cord, and the Musculo-spiral and Circumflex, from the posterior cord. (See plate 12.)

THE BRANCHES of the brachial plexus are as follows:-

Above the clavicle are given off 4, the-

Communicating,—completing the phrenic nerve.

Muscular, to the longus colli, scaleni, rhomboidei, and subclavius muscles. Posterior, or Long Thoracic, external respiratory nerve of Bell,—to the ser-

ratus magnus, arising from the 5th, 6th and 7th cervical.

Suprascapular,—from the 1st trunk of the plexus, to the supra- and infraspinatus muscles and the shoulder joint.

Below the clavicle are 12, namely, the-

Anterior Thoracic 2,—external and internal from the outer and inner cords, to the pectoral muscles.

Subscapular 3,—from the posterior cord, to the subscapularis, teres major and latissimus dorsi muscles.

Circumflex,—from the posterior cord, to the muscles and integument of the shoulder, and the shoulder-joint.

Musculo-cutaneous,—from the outer cord, to the forearm externally, piercing the coraco-brachialis muscle.

Internal Cutaneous,-from the inner cord, to the arm and forearm.

Lesser Internal Cutaneous (nerve of Wrisberg),—from the inner cord, to the back of the arm. Is sometimes wanting, sometimes connected with the intercosto-humeral.

Median,—from outer and inner cords, passes between the two heads of the pronator radii teres, supplying the pronators, flexors, first 2 lumbricales, and the integument of the thumb, 2½ fingers, and the radial side of the palm. Its branches are all in the forearm, except its terminals in the palm of the hand, and are named the—

Muscular.

Anterior Interosseus.
Palmar Cutaneous.

External { Br. to thumb muscles. Digital, to thumb and index. Digital, to thumb, and 2½ fingers.

Ulnar,—from the inner cord, passes between the two heads of the flexor carpi ulnaris at the inner condyle of the humerus, supplying the elbowand wrist-joints, several muscles, and the palmar and dorsal integument of the little finger and half of the ring finger. Branches are the—

Articular (elbow). Dorsal Cutaneous. Superficial Palmar.

Muscular. Articular (wrist). Deep Palmar.

Cutaneous.

Musculo-spiral,—from the posterior cord, accompanies the superior profunda artery and vein in the spiral groove of the humerus, and in front of the external condyle it divides into the radial and posterior interosseous nerves. Its branches are—

Muscular, divided into internal, posterior, and external.

Cutaneous, one internal and two external.

Radial, divides into an external and an internal branch, the latter giving off 4 digital, to the ulnar side of the thumb and the adjacent sides of 2½ fingers.

Posterior Interosseous, supplies all the muscles of the radial side and back of the arm, except 3, also the ligaments and articulations of the carpus.

### THE DORSAL NERVES.

The Dorsal Nerves (Plate 12) are 12 in number on each side. Their posterior divisions pass backward beneath the transverse processes, and divide into internal and external branches, supplying the muscles and integument of the back. Their anterior divisions, the intercostal nerves, are distributed to the walls of the thorax and abdomen, separately from each other, without plexiform arrangement. The 6 upper, except the 1st and the intercosto-humeral branch of the 2nd, are limited in their distribution to the parietes of the chest. The 6 lower supply the walls of the chest and abdomen, the last one sending a cutaneous filament to the buttock. The Lateral Cutaneous nerves are derived from the intercostals, midway between the vertebræ and the sternum; they pierce the external intercostal and serratus

magnus muscles, and divide into anterior and posterior branches. Peculiar among the dorsal nerves and their branches are the—

First Dorsal,—divides into 2 branches, one entering into the brachial plexus, the other forming the 1st intercostal nerve.

Intercosto-humeral,—is the lateral cutaneous branch of the 2d intercostal (anterior division of the 2d dorsal); it pierces the external intercostal muscle and crosses the axilla, joining with a filament from the lesser internal cutaneous (nerve of Wrisberg), supplying the skin of the upper half of the inside and back of the arm, and communicating with the internal cutaneous branch of the musculo-spiral nerve.

Last Dorsal,—is larger than the other dorsal nerves. Its anterior division runs along the lower border of the last rib, and communicates with the first lumbar nerve by the dorsi-lumbar branch, also with the ilio-hypogastric branch of the lumbar plexus. One of its branches, the—

Lateral Cutaneous of the 12th Dorsal,—is also of large size, and is distributed to the integument over the front part of the gluteal region, some of its filaments extending as low as the trochanter major of the femur.

### THE LUMBAR NERVES.

The Lumbar Nerves are 5 in number on each side. Their roots are large and descend vertically in the spinal canal to reach their respective intervertebral foramina of exit. Their posterior divisions pass backward between the transverse processes, and divide into internal branches, supplying the multifidus and interspinales muscles; and external branches, to the erector spinæ and intertransversales muscles and the integument of the gluteal region. Their anterior divisions pass outwardly behind the psoas magnus muscle or between its fasciculi. The anterior divisions of the 4 upper nerves are connected by anastomotic loops, forming the lumbar plexus; that of the 5th with a branch of the 4th forms the lumbo-sacral cord, which joins with the anterior divisions of the 3 upper sacral nerves and part of the 4th to form the sacral plexus. (See plate 14.)

The Lumbar Plexus (Plate 14), is formed by loops from the 12th dorsal and the 4 upper lumbar nerves. It is situated in the substance of the psoas magnus muscle in front of the transverse processes of the lumbar vertebræ. Its branches are given off by the connecting loops, and are as follows:—

Ilio-hypogastric,—from the 1st lumbar nerve, to the integument of the gluteal and hypogastric regions.

Ilio-inguinal,—from the 1st lumbar nerve, to the integument of the upper and inner thigh and to the scrotum

Genito-crural,—from the 1st and 2nd lumbar nerves, to the cremaster

muscle and the integument over the anterior superior part of the thigh.

External Cutaneous,—from the 2nd and 3rd lumbar nerves, to the integument of the anterior, outer and posterior parts of the thigh.

Obturator,—from the 2nd, 3rd and 4th lumbar nerves, through the obturator foramen, to the obturator externus and adductor muscles of the thigh, the hip- and knee-joints, and occasionally the integument of the thigh and leg.

Accessory Obturctor (often absent),—from the 3rd and 4th lumbar nerves, to the pectineus muscle and the hip-joint.

Anterior Crural,—from the 2nd 3rd, and 4th lumbar nerves, to the iliacus and pectineus muscles, all the muscles on the front of the thigh except the tensor fasciæ femoris, the hip- and knee-joints, and the integument on the front and inner side of the thigh. It descends through the psoas magnus muscle, passing beneath Poupart's ligament to the thigh, where it divides into an anterior and a posterior division. Its branches are—

Muscular, within the abdomen, to the iliacus muscle.

Arterial, within the abdomen, to the femoral artery.

Middle Cutaneous, to the skin on the front of the thigh.

Internal Cutaneous, to the skin on the knee and leg.

Muscular, to the pectineus and sartorius muscles.

Long Saphenous, to the skin over the patella and that on the front and inner side of the leg.

Muscular, to the quadriceps extensor muscle.

Articular Branches, to the hip- and knee-joints.

## THE SACRAL AND COCCYGEAL NERVES.

The Sacral Nerves number 5, the Coccygeal 1, on each side. Their roots are long and descend vertically in the spinal canal as the cauda equina or horse's tail, to reach their respective foramina of exit. Their posterior divisions are small; they supply the multifidus spinæ muscles and the skin of the glutcal region; those of the 2 lower sacral and the coccygeal supplying the extensor coccygis and the skin over the coccyx. Their anterior divisions communicate with the sacral ganglia of the sympathetic; those of the 3 upper sacral, with the lumbo-sacral cord and a branch from the 4th sacral, unite to form the sacral plexus. The anterior division of the 4th sacral divides into visceral and muscular branches, the former supplying the pelvic viscera, the latter the levator ani, sphincter ani, and coccygeus muscles. The anterior division of the 5th sacral and the coccygeal supply the coccygeus muscle and the skin over the coccyx.

The Sacral Plexus (Plate 14),—is formed by the union of the anterior

divisions of the 3 upper and part of the 4th sacral nerves (c), with the lumbosacral cord (a) derived from the 4th and 5th lumbar nerves. The plexus lies upon the pyriformis muscle, is covered by the pelvic fascia, communicates

with the sympathetic, and gives off 2 great nervetrunks or cords the *upper cord* being prolonged as the great sciatic nerve, the *lower cord* becoming the pudic nerve, both passing out of the pelvis by the great sacro-sciatic foramen. The branches of the sacral plexus are as follows:—

Muscular Branches,—to the pyriformis, obturator internus, the 2 gemelli and the quadratus femoris.

Superior Gluteal (b),—from the lumbo-sacral cord, to the gluteus medius and minimus muscles and the tensor fasciæ femoris.

Inferior Gluteal,—from the lumbo-sacral cord and the 1st and 2nd sacral nerves, to the gluteus maximus muscle.

Small Sciatic (f),—from the 2nd and 3rd sacral nerves, to the integument of the perineum and back part of the thigh and leg, by gluteal, perineal and femoral cutaneous branches.

Perforating Cutaneous,—from the 2nd and 3rd sacral nerves, to the skin over the gluteus maximus muscle.

Pudic (e),—from the 3rd and 4th sacral nerves, escapes by the great sacro-sciatic foramen, crosses the spine of the ischium, and re-enters the pelvis through the lesser sacro-sciatic foramen, to supply the perineum, anus and genitalia. Its branches are the—

Inf. Hemorrhoidal. Perineal.

Dorsal Nerve of the Penis.

Great Sciatic (g),—the largest nervous cord in the body, and the continuation of the upper cord of the sacral plexus, arises from the lumbo-sacral cord and the 4 upper sacral nerves, and es-

capes by the great sacro-sciatic foramen to the back of the thigh, giving off—

Articular Branches, to the hip-joint.

Muscular Branches, to the flexor muscles of the leg, viz.—the biceps,

semitendinosus and semimembranosus, also to the adductor magnus.

External (h) and Internal (i) Popliteal, the terminal branches, generally arising at the lower third of the thigh.

The Internal Popliteal Nerve (i), the larger of the two terminal branches of the great sciatic, descends along the back of the lower thigh and the middle of the popliteal space, to the lower part of the popliteus muscle, where it becomes the Posterior Tibial Nerve (k). Its branches are the—

Articular 3,-supplying the knee-joint.

Muscular (j), 4 or 5,—to the gastrocnemius, plantaris, soleus and popliteal muscles.

Communicans Tibialis,—joins the communicans peronei from the external popliteal nerve to form the—

External or Short Saphenous (2),—descends to the outer malleolus and is distributed to the skin of the outer side of the foot and the little toe.

The Posterior Tibial Nerve (k), the continuation of the internal popliteal, descends along the back of the leg to behind the inner malleolus, where it divides into the External and Internal Plantar nerves (l). Its branches are the—

Muscular,—to the soleus, tibialis posticus, flexor longus digitorum and flexor longus hallucis.

Calcaneo-plantar or Internal Calcanean,—to the skin of the heel and inner side of the sole of the foot.

Articular,—to the ankle-joint.

Internal Plantar,—to the inner plantar muscles, sole of the foot, and the plantar integument of the inner 3½ toes.

External Plantar,—to the external plantar muscles, and the plantar integument of the outer 1½ toes.

The External Popliteal or Peroneal Nerve (h), the smaller of the two terminal branches of the great sciatic, descends from the bifurcation of the latter nerve, obliquely along the outer side of the popliteal space, winds around the neck of the fibula, and about an inch below the head of that bone it divides into the Anterior Tibial (m) and Musculo-cutaneous (n) nerves. Its branches are—

Articular, 3,—to the front and outer side of the knee.

Cutaneous, 2 or 3,—to the integument along the back and outer side of the leg. One of these branches, the—

Communicans Peronei,—joins with the communicans tibialis (see above) to form the external saphenous nerve.

Anterior Tibial (m),—supplying the extensor muscles, the ankle-joint, and the integument of the adjacent sides of the great and 2d toes.

Musculo-cutaneous (n),—by 2 branches (o) (internal and external) to the peroneal muscles, the integument of the ankles, and the dorsal integument and sides of all the toes, except the outer side of the little toe and the adjoining sides of the great and 2d toes, the former being supplied by the external saphenous, and the latter by the internal branch of the anterior tibial.

#### THE SYMPATHETIC NERVE.

The Sympathetic Nervous System consists of—a series of ganglia, connected together by intervening cords, one series on each side of the median line of the body, partly in front and partly on each side of the vertebral column, beginning in the ganglion of Ribes on the anterior communicating artery and ending in the ganglion impar in front of the coccyx; three great gangliated plexuses, situated in the thoracic, abdominal, and pelvic cavities respectively; smaller ganglia, in relation with the abdominal viscera; and numerous communicating and distributing nerve fibres. (See plate 16.)

Ganglia in the Cranium. Besides the ganglia of the cranial nerves (described on page 197), all of which are connected with the sympathetic, there are in the cranium or in its immediate vicinity certain ganglia belonging to the sympathetic system, as follows:—those which are doubtful or disputed having the mark (?)—

Ganglion of Ribes (?),—on the anterior communicating artery, connecting the two gangliated cords together.

Carotid Ganglion,—on the internal carotid artery.

Ganglion of Cloquet (?),—in the incisive fossa, on the naso-palatine nerve. Ganglion of Bochdalek (?),—above the canine tooth at the junction of a branch from the spheno-palatine ganglion with the middle superior dental and anterior superior dental nerves.

The Carotid Plexus is situated on the outer side of the internal carotid artery, as it lies by the side of the body of the sphenoid bone, and is formed by filaments from the outer branch of the superior cervical ganglion. It communicates with the Gasserian ganglion and the 6th nerve; also with the tympanic branch of the 9th by two branches, the small deep petrosal and the carotico-tympanic; and with the spheno-palatine ganglion by the large deep petrosal, which joins the great superficial petrosal to form the Vidian nerve before entering the ganglion (see page 200).

The Cavernous Plexus is situated in the upper portion of the cavernous

sinus, below the last bend of the internal carotid artery, and is formed chiefly by the internal division of the ascending branch from the superior cervical ganglion. It communicates with the 3rd, 4th, ophthalmic division of the 5th, and the 6th nerves, also with the ophthalmic ganglion. It sends filaments to the wall of the internal carotid artery, which are prolonged into plexuses around the cerebral and ophthalmic arteries. The filaments on the anterior communicating artery form the ganglion of Ribes, which here connects the sympathetic of the two sides of the body.

#### THE GANGLIATED CORD.

The Cervical Ganglia are 3 in number on each side of the neck, the superior, middle and inferior cervical; of which the superior is the largest and is probably formed by the coalescence of four ganglia corresponding to the four upper cervical nerves. They are as follows:-

Superior Cervical Ganglion,—of fusiform shape, situated behind the carotid sheath opposite the 2d and 3d cervical vertebræ. Its branches form the carotid, cavernous, and pharyngeal plexuses; one of its internal branches unites with the superior laryngeal nerve, and another is the superior cardiac nerve going to the cardiac plexuses.

Middle Cervical Ganglion,—on the inferior thyroid artery, opposite the 6th cervical vertebra gives off the middle cardiac nerve to the deep cardiac plexus, also many communicating branches.

Inferior Cervical Ganglion,—on the superior intercostal artery, between the neck of the 1st rib and the transverse process of the 7th cervical vertebra. It gives off several communicating branches and the inferior cardiac nerve to the deep cardiac plexus.

The Thoracic Ganglia are 11 or 12 in number on each side of the spine, resting against the heads of the ribs and covered by the pleura costalis, except the last two, which are placed on the side of the bodies of the 11th and 12th dorsal vertebræ. Occasionally two ganglia coalesce into one, and the first is frequently blended with the last cervical ganglion. They are connected together by cords prolonged from their substance. They give off external branches connecting with the dorsal spinal nerves; and internal branches from the 5 or 6 upper ganglia to the thoracic aorta, etc., from the 3rd and 4th ganglia to the posterior pulmonary plexus, and from the 6 or 7 lower ganglia to form by their union the three splanchnic nerves, as follows:-

Great Splanchnic,—from branches of the 6th to the 10th, connecting with the upper six, passes through the posterior mediastinum, perforates the crus of the diaphragm, to the semilunar ganglion of the solar plexus.

Lesser Splanchnic,—from the 10th and 11th, passes through the diaphragm with the great splanchnic, to the solar plexus. 14

Smaller or Renal Splanchnic,—from the last thoracic ganglion, also perforates the diaphragm, and ends in the renal and solar plexuses.

The Lumbar Ganglia consist usually of 4 small ganglia on each side, connected together by intervening cords, and situated in front of the vertebral column. Their external branches communicate with the lumbar spinal nerves. Of their internal branches some help to form the aortic plexus, others go to the hypogastric plexus, and all give off numerous filaments to the bodies of the lumbar vertebræ and the ligaments connecting them.

The Pelvic Ganglia are 4 or 5 small ganglia on each side, connected together by intervening cords, and situated in front of the sacrum. The lower cords of each side converge below and unite on the front of the coccyx in the coccygeal ganglion or ganglion impar. Their external branches, 2 from each ganglion, communicate with the sacral nerves. Of the internal branches, some pass to the pelvic plexus, others go to a plexus on the middle sacral artery and all communicate on the front of the sacrum with the corresponding branches of the other side.

### THE GREAT PLEXUSES (Plate 16).

The Great Plexuses of the Sympathetic are large aggregations of nerves and ganglia, situated in the thoracic, abdominal, and pelvic cavities, and named the Cardiac Plexus, the Epigastric or Solar Plexus, and the Hypogastric Plexus. Their branches form secondary plexuses which supply the viscera of the cavities, as described below.

The Cardiac Plexus is situated at the base of the heart, and is divided into a superficial portion and a deep portion, both of which are closely connected with each other. They form by their branches the anterior and posterior coronary plexuses and the anterior pulmonary plexus.

The Superficial Cardiac Plexus is formed by the left superior cardiac nerve, the left inferior cervical cardiac branches of the pneumogastric, and filaments from the deep cardiac plexus. At the junction of these nerves a small ganglion, the cardiac ganglion of Wrisberg, is occasionally found, situated immediately beneath the arch of the aorta. This plexus lies in the concavity of the arch of the aorta, and in front of the right pulmonary artery. Branches from it pass to the—

Anterior Coronary Plexus,—formed chiefly from the preceding, also from the deep cardiac plexus. It passes forward between the aorta and the pulmonary artery, to the anterior surface of the heart.

Anterior Pulmonary Plexus,—is formed by filaments from the superficial and deep cardiac plexuses and the anterior pulmonary branches of the

pneumogastric nerve. Branches from it accompany the ramifications of the bronchial tubes throughout the lungs. [The *Posterior Pulmonary Plexus* is formed by the posterior pulmonary branches of the pneumogastric and branches from the 3rd and 4th thoracic ganglia of the sympathetic. It is not connected with the cardiac plexuses. It is situated on the posterior aspect of the root of the lungs, and its branches accompany the ramifications of the bronchial tubes.]

The Deep Cardiac Plexus is formed by the cardiac nerves derived from the cervical ganglia of the sympathetic and the cardiac branches of the recurrent laryngeal and pneumogastric nerves. The only cardiac nerves which do not enter into its formation are those forming the superficial cardiac plexus, namely—the left superior cardiac and the inferior cervical cardiac branches of the pneumogastric. This plexus lies in front of the bifurcation of the trachea and behind the arch of the aorta. Its branches on the right side pass in front and behind the right pulmonary artery to the anterior pulmonary plexus, the anterior and posterior coronary plexuses, and the right auricle; those on the left side give filaments to the superficial cardiac and anterior pulmonary plexuses and the left auricle, and then form the greater part of the—

Posterior Coronary Plexus,—is formed by filaments from both sides of the deep cardiac plexus. It surrounds the branches of the right coronary artery at the back of the heart, and its filaments are distributed with those vessels to the muscular substance of the ventricles.

Ganglia,—are found on the cardiac nerves, both on the surface of the heart and in its muscular substance.

The Epigastric or Solar Plexus, sometimes called the abdominal brain, consists of a great network of nerves and ganglia, situated behind the stomach and in front of the aorta and the crura of the diaphragm, surrounding the coeliac axis and the root of the superior mesenteric artery. Its principal ganglia are the two Semilunar Ganglia, irregular gangliform masses, formed by the aggregation of smaller ganglia with interspaces between them, situated one on each side of the plexus, and in front of the crura of the diaphragm, close to the supra-renal capsules. This plexus and its connected ganglia receive the great and small splanchnic nerves of both sides, and some filaments from the right pneumogastric. It distributes filaments over all the branches from the front of the abdominal aorta, forming the following plexuses;—

Phrenic or Diaphragmatic Plexus,—arises from the upper part of the semilunar ganglion, and receives one or two branches from the phrenic nerve. It accompanies the phrenic artery and supplies the diaphragm, some

- filaments going to the supra-renal capsule. At its junction with the phrenic nerve on the right side is the—
- Ganglion Diaphragmaticum,—a small ganglion on the under surface of the diaphragm, near the right supra-renal capsule.
- Supra-renal Plexus,—is formed by branches from the solar plexus, the semilunar ganglion, the phrenic and great splanchnic nerves. Its branches are large, and supply the supra-renal capsule.
- Renal Plexus,—is formed by filaments from the solar plexus, the semilunar ganglion, the aortic plexus, and the lesser and smallest splanchnic nerves, some 15 or 20 in all, which have numerous ganglia on them. They accompany the branches of the renal artery into the kidney, some filaments going to the inferior vena cava and to the spermatic plexus.
- Spermatic Plexus,—is derived from the renal plexus and receives filaments from the aortic plexus. It accompanies the spermatic vessels to the testes. In the female it is called the Ovarian Plexus, and is distributed to the ovaries and the fundus of the uterus.
- Cæliac Plexus,—is a direct continuation of the solar plexus, receives branches from the lesser splanchnic nerves and a filament from the right pneumogastric. It surrounds the cœliac axis, and subdivides into the gastric, hepatic, and splenic plexuses.
- Gastric or Coronary Plexus,—joins with branches from the left pneumogastric nerve, and accompanies the gastric artery along the lesser curvature of the stomach, being distributed to that viscus.
- Hepatic Plexus,—receives filaments from the left pneumogastric and the right phrenic nerves, accompanies the hepatic artery, and ramifies in the substance of the liver upon the branches of that artery and those of the portal vein. It gives off branches to all the divisions of the hepatic artery, forming pyloric, gastro-duodenal, gastro-epiploic, and cystic plexuses, on the arteries similarly named.
- Splenic Plexus,—is formed by branches from the coeliac plexus, the left semilunar ganglion, and the right pneumogastric nerve. It accompanies the splenic artery and its branches to the substance of the spleen, and gives off filaments to the pancreas and the left gastro-epiploic plexus.
- Superior Mesenteric Plexus,—is a continuation of the solar plexus, and receives a branch from the right pneumogastric nerve. It surrounds the superior mesenteric artery, and divides into pancreatic, intestinal, ileo-colic, right colic, and middle colic branches, which are distributed to all the parts supplied by that artery. Its nerves have numerous ganglia upon them near their origin.
- Aortic Plexus,—on the sides and front of the aorta, between the origins of the superior and inferior mesenteric arteries; is formed by branches from

the solar plexus and semilunar ganglia, and receives filaments from the lumbar ganglia. It sends branches to the spermatic inferior mesenteric, and hypogastric plexuses, also some filaments to the inferior vena cava. A part of it is the—

Inferior Mesenteric Plexus,—divides into left colic, sigmoid, and superior hæmorrhoidal plexuses, and supplies the descending colon and the rectum.

The Hypogastric Plexus is formed by filaments from the aortic plexus and the lumbar ganglia, and is situated in front of the promontory of the sacrum between the two common iliac arteries. It contains no evident ganglia, and bifurcates into two lateral divisions, the Pelvic or Injerior Hypogastric Plexuses, one on each side of the rectum, which receive branches from the 2nd, 3rd, and 4th sacral nerves, and the first two sacral ganglia. They give off numerous branches along the branches of the internal iliac arteries to the pelvic viscera, forming the following secondary plexuses, viz.—

Inferior Hæmorrhoidal Plexus,—to the rectum.

Vesical Plexus,—to the bladder, vesiculæ seminales, and vas deferens.

Prostatic Plexus,—to that gland and the vesiculæ seminales, also to the erectile tissue of the penis as the large and small cavernous nerves.

Vaginal Plexus,—to the vagina in the female.

Uterine Plexus,—to the uterus and Fallopian tube, in the female.

### TABLES AND PLATES

OF THE

## NERVOUS SYSTEM.

NOTE.—The following Tables are of original arrangement, and are designed to show the origin, formation and distribution of each nerve. They are self-explanatory with the aid of the accompanying Plates.

#### THE CRANIAL NERVES.

1st NERVE,-Olfactory. in cribriform plate of Function,-smell. Ext. Filaments, to Schneiderian mem-Ext. Root, Limbic lobe. 1st N. brane over sup, turbinated and ethmoid Mid. Root, Optic thalamus. and Bulb. bones. Int. Root, Limbic lobe. Int. Filaments, to Septum (upper third). 2d NERVE,-Optic. Function,-sight. Exit,-Optic foramen. Nucleus in floor of the Aqued. of Syl. Crus cerebri.

3d N. 

Sup. Branch, to Lev. palp. sup., Rectus superior. fto Rectus int., Rect. inf., Inf. oblique. motor root to Ciliary Ganglion.

Supplies all the muscles of the orbit (except the superior oblique and ext. rectus), also the sphincter of the iris and the ciliary muscle through the ciliary ganglion.

Aq. of Sylvius.
Crus cerebri.

4th N. 

Function,—motion. 

Exit,—Sphenoidal fissure.

Function,—motion. 

Exit,—Sphenoidal fissure.

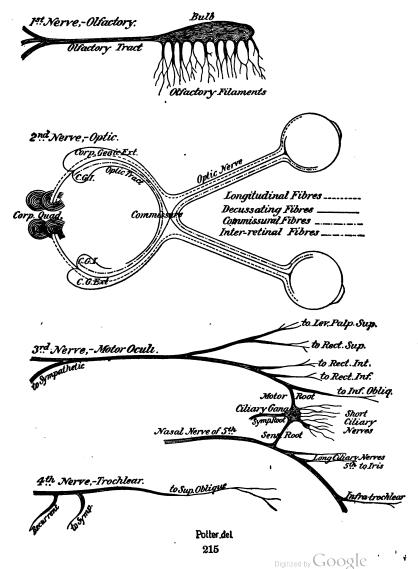

Sup. Oblique on upper (orbital) surface.

Branch to Cavernous Plexus of Sympathetic.

Recurrent Branch, to lateral sinus.

Is the smallest cranial nerve, with the longest nerve-course in the cranial cavity.

Ethmoidal foramina, 20,

# THE SYMPATHETIC SYSTEM OF NERVES.

Plate 16.

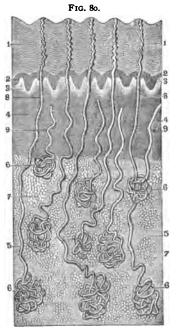

## ORGANS OF SPECIAL SENSE.

The Special Senses are those of touch, taste, smell, sight and hearing. The Skin is the principal seat of the sense of touch, the Tongue is the organ of taste, the Nose is the peripheral organ of smell, the Eye of sight and the Ear of hearing.

### THE SKIN AND ITS APPENDAGES.

The Skin consists of—the *Epidermis* or *Cuticle*, the scarf-skin, composed of 3 superficial and 2 deep layers; and the *Derma*, *Corium*, or

Cutis Vera, the true skin, composed of a papillary layer above and a reticular layer below.

The Epidermis, Cuticle or Scarfskin, is an unorganized epithelial structure, having neither vessels nor nerves. Its constituent epithelial cells are agglutinated together in a laminated arrangement, are flat and dry on the surface, round and softer in the central portion, columnar and softest in the deepest layers. They are arranged in the following layers, from above downward, viz.—

Stratum Corneum (1),—horny epithelial cells, without nuclei.

Stratum Lucidum,—closely packed, scaly cells.

Stratum Granulosum,—flat, spindleshaped cells, containing granules of *eleidin*, an intermediate substance in the formation of horn.

Rete Mucosum or Stratum Malpighii (2),—contains pigment cells. Basilar Layer or Stratum Germinativum,—composed of columnar

epithelial cells placed perpendicularly on the surface of the derma, and separated from the papillæ by a homogeneous basement membrane.

The Derma, Corium or Cutis Vera (4), the true skin, is a highly organized,

tough yet elastic tissue, and serves to protect the parts beneath, to perform the functions of excretion and absorption, and as the chief seat of the sense of touch. It consists of felted connective tissue, elastic fibres, blood-vessels, lymphatics, and nerves; also unstriped muscular fibres in various situations. It is formed in two layers, as follows:—

Papillary Layer (3),—situated next to the epidermis, is covered with minute conical elevations (papillæ),  $_{100}^{-1}$  inch high,  $_{200}^{-1}$  inch in diameter at their base, very numerous and arranged in parallel curved lines wherever sensibility is greatest. Each papilla contains a capillary loop or plexus, the termination of one or more sensory nerves,—and in highly sensitive parts, an oval-shaped body, the Tactile Corpuscle, a special sensory nerve ending.

Reticular Layer,—the deep layer, is composed chiefly of interlacing bundles of white fibrous tissue, in which are mingled some yellow elastic fibres; also plain muscular fibres wherever hairs are found, and lymphatic vessels, blood-vessels, and nerves in plexiform arrangement. Below this the elements of the skin become blended with the subcutaneous areolar tissue (5), which contains fat, except in a few situations.

Mucous Membrane is a soft, velvety structure, analogous to the skin, and found as the lining of the gastro-intestinal, pulmonary and genito-urinary tracts. It is composed of—*Epithelium* of various forms, including the squamous, columnar, and ciliated, often arranged in several layers; and *Corium*, analogous to the derma of the skin, consists of connective tissue, blood-vessels, lymphatics, nerves, and unstriped muscle cells; and is separated from the epithelium by a transparent basement membrane. The mucous membrane has numerous *glands* embedded in it, which secrete *mucus* to cover the surface for its protection from foreign substances. Projecting from it in certain parts are *villi* and *papillæ*, processes which are analogous to the papillæ of the skin.

Structures lying in the Skin and directly beneath it, include the following, viz.—

Sensitive Papillæ, containing Tactile Corpuscles in very sensitive parts,—in the papillary layer of the derma.

Hair Follicles,—in the reticular layer of the derma, perforating the derma and the epidermis: sometimes extending into the subcutaneous tissue.

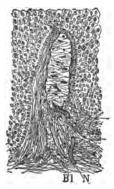

Sebaceous Glands (6),—in the reticular layer of the derma; their ducts (8, 9) opening usually into the hair-follicles, but occasionally on the surface of the epidermis.

Sudoriferous or Sweat Glands,—usually in the subcutaneous areolar

tissue; their ducts perforating the derma and epidermis, to open on the surface of the latter.

Fat Cells,—in the subcutaneous areolar tissue.

FIG. 81.

Organs of Touch are the various sensory nerve-endings in the skin or its vicinity and in mucous membranes. They include minute, primitive fibrilla or networks thereof, and certain special terminal organs, as follows:—

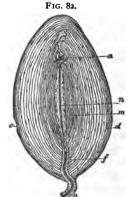

End-bulbs of Krause,—minute bodies, \$\frac{1}{600}\$ incn in diameter, consisting of a capsule surrounding a soft core, in which the axis-cylinder of the nerve terminates, in a bulbous expansion or in a coiled plexiform mass. They are found chiefly in mucous membranes, the genital organs, and the synovial membranes of the finger-joints.

Tactile Corpuscles,—are oval bodies,  $\frac{1}{300}$  inch long, formed of connective tissue, and con-

sisting of a capsule and imperfect septa, which penetrate the interior. The axis-cylinders of the nerve fibres (N) terminate within the corpuscle in a globular enlargement. They are found in papillæ of

the derma of the hand, foot, forearm, lips, nipple, etc. Other tactile corpuscles, in the papillæ of parts devoid of hair, consist of a capsule, containing two or more granular cells, between which the nerve-fibre is supposed to terminate.

Pacinian Corpuscles,—are composed of lamellæ (d), consisting of connective tissue fibres, arranged concentrically around a central clear space (m), in which the nerve-fibre (n) terminates at the distal extremity in a rounded end (a), which is often bifid or even trifid. They are found chiefly on the nerves of the palm of the hand and the sole of the foot, the ends of the fingers, and the genital organs, lying in the subcutaneous tissue.

## APPENDAGES OF THE SKIN.

The Nails are curved, horny structures, a modification of the epidermis, molded upon the derma at the dorsal surface of the terminal phalanges

of the fingers and toes. Each nail is convex on its outward surface, and is embedded by its *Root* into a fold of the skin. Its—

Matrix,—is that portion of the derma directly beneath the nail. It is covered with highly vascular papillæ. The—

Lunula,—is a white crescentic portion of the nail nearest to its root, produced by the diminution in number and size of the papillæ beneath.

The Hairs are also a modified form of the epidermis, found over nearly the whole surface of the body, much varied in size and color. Each hair consists of a Root and a Shaft. The—

Root,—is lodged in an involution of the epidermis called the Hair-jollicle, which sometimes extends into the subcutaneous cellular tissue. The root rests on a vascular papilla, at the bottom or Bulb of the follicle-which supplies it with material for its growth.

Shaft,—is the projecting portion of the hair. It consists of a medulla in the centre, next a fibrous portion, externally a cortex of thin, flat scales. The finest hairs have no medulla.

Point,—consists of the fibrous portion and the cortex, the medulla being wanting.

Sebaceous Glands are small, glandular bodies situated in the corium over most of the body, but not in that of the palmar surface of the hands nor on the plantar surface of the feet. Each gland consists of a single sacculated duct, usually opening into a hair follicle, but sometimes ending on the surface of the epidermis. They are most abundant in the scalp, the face, around the anus, and the apertures of the nose, mouth and external ear. The largest are the—

Meibomian Glands,—situated in the eyelids.

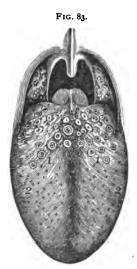

Sudoriferous or Sweat Glands consist each of a single convoluted tube, situated usually in the subcutaneous cellular tissue, and opening on the surface of the integument by a spiral duct which pierces the derma and the epidermis. The duct has two coats, an external fibro-cellular, which is continuous with the corium, and an epithelial lining, continuous with the epidermis. These glands are estimated as varying, in different parts of the integument, from 417 to 2800 to the square inch, giving for the whole body a total number of nearly two millions and a half, representing an evaporating surface of about 8 square inches. They are most numerous on the palm of the hand.

#### THE TONGUE.

The Tongue is the organ of taste. It consists of its intrinsic muscles (see below), is covered with mucous membrane, and is supplied with blood-

vessels, lymphatics and nerves. Its base is connected with the hyoid bone by the hyo-glossi and genio-hyo-glossi muscles and the hyo-glossal membrane; with the epiglottis, by the 3 glosso-epiglottic folds of mucous membrane; with the soft palate, by the anterior pillars of the fauces; and with the pharynx, by the superior constrictor muscles and the mucous membrane. Its tip, thin and narrow, is free in the mouth, and rests when quiet against the lower incisor teeth. Its under surface is connected with the lower jaw by the genio-hyo-glossi muscles. Its mucous covering is reflected laterally on the inner surface of the gums, forming in front the frænum linguæ, a vertical fold below the tip. The tongue presents the—

Raphé,—a vertical, fibrous septum, in the median line, dividing the tongue into two symmetrical halves, and terminating behind in a depression, the *joramen cœcum*, about an inch from the base of the organ.

Papillæ Maximæ (1) (circumvallate),—8 to 12 in number, in two rows on the dorsum of the tongue, the rows forming a V and meeting in front of the foramen cæcum.

Papillæ Mediæ (2) (fungiform),—scattered irregularly over the dorsum, chiefly at its sides and apex.

Papillæ Minimæ (filiform),—cover the anterior two-thirds of the dorsum and have numerous filiform processes or secondary papillæ projecting from their apices.

Papillæ Simplices,—similar to those of the skin, cover the whole organ, as well as the larger papillæ.

Taste-buds,—flask-shaped bodies, found in the epidermis of the circumvallate papillæ, and in some of the fungiform (described below).

Mucous Glands,—found especially at the back of the tongue, but are also present at the apex and sides.

Glands of Blandin or Nuhn,—mucous glands, one on either side of the frænum, having 4 to 6 ducts which open on the under surface of the apex.

Racemose Serous Glands,—at the back of the tongue, their ducts opening into the fossæ of the circumvallate papillæ.

Hyo-glossal Membrane,—a strong, fibrous lamina, connecting the under surface of the base of the tongue to the body of the hyoid bone.

Extrinsic Muscles of the Tongue,—are the stylo-, hyo-, chondro-, geniohyo-, palato-glossi muscles, and part of the superior constrictors of the pharynx (pharyngeo-glossi). These have been described on page 82.

Intrinsic Muscles of the Tongue,—are the various fibres of the lingualis muscle,—superior, inferior, transverse and vertical. (See page 82.)

Taste-buds are flask-shaped bodies, situated in the epidermis (e) of the circumvallate and some of the fungiform papillæ; also found at the sides of

the base of the tongue, on the epiglottis and the soft palate. Each bud has a broad base, which rests on the corium, and a neck opening on the mucous surface by an orifice, the gustatory pore (o). The buds are formed by supporting cells, mostly arranged like the staves of a cask; and spindle-shaped, nucleated gustatory cells in the central portion, each terminating at the gustatory pore in a fine filament, the gustatory hair. Terminal nerve-fibrils ramify between the gustatory cells, and others are found between the cortical cells.

FIG. 84.

Vessels of the Tongue. The Arteries are derived from the lingual, facial, and ascending pharyngeal branches of the external carotid. The

Veins open into the internal jugular. The Lymphatics pass to one or two small glands on the hyo-glossus muscle, and thence to the deep glands of the neck.

## Nerves of the Tongue are as follows: the-

Lingual Branch of the 5th,—to the papillæ of the fore part and sides of the tongue, endowing the anterior two-thirds of the organ with ordinary sensibility.

Chorda Tympani Branch of the 7th,—runs in the sheath of the lingual and is distributed to the same region, being the nerve of taste for the anterior two-thirds of the tongue.

Lingual Branches of the 9th or Glosso-pharyngeal,—to the mucous membrane of the base and sides and the circumvallate papillæ, being the nerves of taste and ordinary sensation for the posterior third of the tongue.

Hypo-glossal or 12th Nerve,—the motor nerve of the tongue, distributed to the intr nsic and extrinsic muscles.

Superior Laryngeal Branch of the 10th or Pneumogastric,—sends a tew filaments to the root of the tongue.

Sympathetic Filaments,—from the nervi molles on the lingual and other arteries supplying the organ.

## Special Nerves of Taste in the Tongue, are the-

Chorda Tympani Branch of the Facial,—for its anterior two-thirds; perceiving saline, acid and styptic qualities (Flint).

Lingual Branches of the Glosso-pharyngeal,—for its posterior third; appreciating alkaline, metallic, sweet and bitter tastes (Flint).

Sapolini's view of the Chorda Tympani Nerve. From repeated dissections, Dr. Sapolini, of Milan, believes the chorda tympani to be a separate cranial nerve, a continuation of the pars intermedia of Wrisberg, which has its deep origin in the upper end of the nucleus of the glosso-pharyngeal nerve in the floor of the 4th ventricle, joins the facial in the internal auditory meatus, and terminates in a dense plexus with the lingual branch of the 5th in the muscular substance of the tongue. He further concludes that the chorda tympani is the nerve governing the movements of the tongue in speech, and that the nerves of taste are the Lingual Branches of the 5th and 9th nerves.

#### THE NOSE.

The Nose is the peripheral organ of smell, and consists of the outer nose and the nasal fossæ. The Outer Nose projects from the centre of the face, and is composed of a framework of bones and cartilages, covered by skin, lined by mucous membrane, and supplied with vessels and nerves. At its base it presents two elliptical orifices, the nostrils or anterior nares, separated by a septum, the columna, and guarded at their margins by numerous stiff hairs, the vibrissæ. The—

Bony Framework,—is formed by the nasal bones and the nasal processes of the superior maxillary: (see page 31).

Cartilages are 5,—two upper lateral, two lower lateral, and the cartilage of the septum, connected together and to the bones by a tough, fibrous membrane, which permits of free movement between them.

Septum Narium, the nasal septum,—is formed anteriorly by the cartilage of the septum, posteriorly by the perpendicular plate of the ethmoid bone above and the vomer below.

The Nasal Fossæ are two irregular cavities in the middle of the face, separated by the septum narium, opening in front by the anterior nares, behind by the posterior nares into the naso-pharynx. Their osteological description has been given on page 41. Each fossa is divided into an oljactory portion, containing the upper part of the septum and the superior turbinated bone, and a respiratory portion, comprising the rest of the fossa. It is further divided, from above downward, into the superior, middle and

inferior meatuses of the nose, which are separated from each other by the middle (2) and inferior turbinated bones. Each fossa presents the—

Vestibule (9),—a slight dilatation inside the aperture of the nostril, extending as a small pouch, the ventricle, toward the point of the nose.

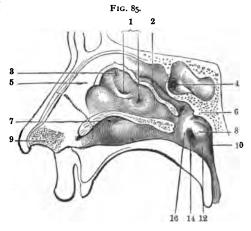

Spheno-ethmoidal Recess,—on the outer wall, above the superior turbinated bone, into which the sphenoidal sinus (4) opens.

Bulla Ethmoidalis,—an elevation on the outer wall of the middle meatus,

on or above which are the orifices of the middle ethmoidal cells.

Hiatus Semilunaris,
—a narrow groove
in the outer wall, in
front of the bulla
ethmoidalis, into
which open the
anterior ethmoidal
cells and the antrum of Highmore (1).

Infundibulum (3), the superior prolongation of the middle meatus,

leading into the frontal sinus: (see page 21).

Atrium (5),—a depressed area above the vestibule, forming the anterior extremity of the middle meatus.

Orifice of the Nasal Duct (7),—on the outer wall, in the anterior part of the inferior meatus.

Naso-palatine Recess,—a depression at the lower edge of the cartilage of the septum; near it a minute orifice leads into a blind pouch, the rudimentary organ of Jacobson.

The Schneiderian or Pituitary Membrane is the mucous membrane lining the nasal fossæ, thick and vascular over the septum and the turbinated bones, but very thin elsewhere. On it, in the upper portion of the fossæ, are distributed the terminal filaments of the oljactory nerve, the special nerve of the sense of smell. It is continuous with the mucous lining of the pharynx, Eustachian tube, tympanum and mastoid cells; also with that of the frontal, ethmoidal and sphenoidal sinuses, the antrum, nasal duct, and the con-

junctiva. It is covered with columnar epithelium, which is ciliated throughout most of its extent, contains much adenoid tissue, is provided with mucous and serous glands, and in the olfactory region it contains the-

Oljactory Cells of Schultze,-spindle-shaped, epithelial cells, grouped around and between the columnar cells of the epithelium, having at one end hair-like processes, the olfactory hairs, and joined together by other processes, forming an intricate plexus on which the terminal fibres of the olfactory nerves are supposed to end.

Glands of Bowman,—are tubular, often branched, serous glands, in a layer beneath the epithelium, extending through the thickness of the mucous membrane, in the olfactory region.

Muscles of the Nose are on each side the pyramidalis nasi, levator labii superioris alæque nasi, dilator naris, compressor nasi, compressor narium minor, and depressor alæ nasi. They are described on page 77.

**Nerves** supplying the Outer Nose are branches from the facial nerve to the muscles; branches from the infraorbital and infratrochlear, and the

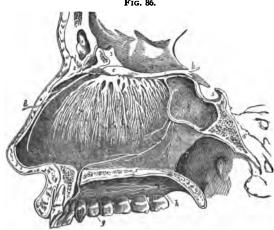

Fig. 86.

nasal branch of the ophthalmic, supplying the integument. Those supplying the Nasal Fossæ are the-

Olfactory or 1st Nerve (a),—over the upper third of the septum (i), the superior turbinated bone and the surface of the ethmoid in front of it Nasal Branch of the Ophthalmic (d),—to the septum and outer walls.

Anterior Dental Branch of the Superior Maxillary,—to the inferior meatus of the nose and the inferior turbinated bone.

Vidian Nerve,—to the septum and the inferior turbinated bone.

Naso-palatine (e),—from the spheno-palatine ganglion, to the middle of the septum; thence through the anterior palatine foramen (f).

Anterior Palatine (h),—from the spheno-palatine ganglion, to the middle and lower turbinated bones, by its inferior nasal branches.

Superior Nasal Branches,—from the spheno-palatine ganglion, to the septum and the superior and middle turbinated bones.

Arteries of the Nose. The arteries supplying the Outer Nose are—the lateralis nasi branch of the facial; the inferior artery of the septum, from the superior coronary branch of the facial; and the nasal branch of the ophthalmic and the infraorbital, which go to the dorsum and sides of the nose. The Arteries of the Nasal Fossæ form a close, plexiform network beneath and in the mucous membrane, and are the—

Ant. and Post. Ethmoidal, from the ophthalmic,—to the roof.

Spheno-palatine, branch of the internal maxillary,—to the mucous membrane over the turbinated bones, the meatuses, and the septum.

Infraorbital and Alveolar, branches of the internal maxillary,—to the mucous lining of the antrum.

Inferior Artery of the Septum, from the superior coronary branch of the facial,—to the mucous membrane of the septum.

Veins of the Nose. Those of the outer nose terminate in the facial and ophthalmic veins. Those of the nasal fossæ form a close, cavernous-like network beneath the mucous membrane, and terminate in the facial and ophthalmic veins, a few going to the veins in the interior of the skull.

#### THE EYE.

[For an osteological description of the Orbit, see page 39.]

The Eyeball is situated in the anterior part of the orbital cavity, on a cushion of connective tissue and fat, where it is retained by its muscles, the optic nerve, the conjunctiva, etc., and protected in front by the eyelids and eyebrows. It is composed of segments of two spheres of different sizes; the anterior segment being the smaller, forming about \$\frac{1}{2}\$th of the eyeball, and named the cornea; the posterior and larger segment, is formed by the sclerotic coat, and constitutes the remaining \$\frac{5}{2}\$ths of the globe. It is surrounded by a thin, membranous sac, the capsule of Tenon, and has the following—

Diameters,—in the adult, antero-posterior and transverse, nearly an inch; vertical about  ${}_{10}^{\circ}$ ths of an inch.

Anterior Pole,—the central point of the anterior curvature.

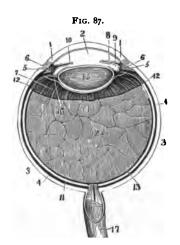

Posterior Pole,—the central point of the posterior curvature.

Sagittal Axis,—a line joining the two poles.

The Capsule of Tenon (3) is a thin membrane which envelops the eyeball from the optic nerve to the ciliary region, where it blends with the ocular conjunctiva. Its smooth, inner surface is in contact with the outer surface of the sclerotic, with which it is connected by delicate bands of connective tissue. Posteriorly it is continuous with the sheath (17) of the optic nerve, and from it tubular sheaths are prolonged over the muscles which move the eyeball, giving off slips to the bones of the orbit. The—

Check Ligaments,—internal and external, are expansions from the sheaths of the internal and external recti muscles, and are attached to the lachrymal and malar bones respectively.

Suspensory Ligament of the Eye,—is a thickening of the lower part of the

capsule, slung like a hammock below the eyeball, and attached to the lachrymal and malar bones.

Peri-sclerotic Lymph-space,—intervenes between the capsule and the sclerotic, and is continuous with the subdural and subarachnoid spaces.

Tunics of the Eyeball are 3 in number, named from without inward as follows; the—

Sclerotic (3) and Cornea (1),—the external, fibrous, and protective tunic.

Choroid (4), Ciliary Body (5), and Iris (8),—the vascular tunic, sometimes called the Uveal Tract.

Retina (13),—the innermost, nervous tunic.

Refracting Media are 3 in number, and are named as follows; the— Aqueous Humor (2),—fills the anterior (2) and posterior (9) chambers. Vitreous Body (18),—fills the concavity of the retina. Crystalline Lens (15),—in front of the vitreous body.

#### THE SCLEROTIC AND CORNEA.

The Sclerotic, or hard coat, is the posterior five-sixths of the external tunic of the eyeball, the anterior one-sixth being the Cornea. Externally it is of a white color, covered anteriorly by the conjunctival mucous membrane, posteriorly being continuous with the fibrous sheath of the optic nerve. Internally its color is brown, and its surface marked by grooves for the ciliary nerves. The optic nerve pierces it posteriorly, also the long and short ciliary arteries, posterior ciliary veins and short ciliary nerves. In the equatorial region it is pierced obliquely by the venæ vorticosæ, and around the corneal border by the anterior ciliary arteries and veins. It is composed of white fibrous tissue, intermixed with elastic fibres, and of flattened connective-tissue corpuscles, some of which are pigmented. The Sclerotic presents for consideration the following points:—

Thickness,— $\frac{1}{25}$  inch posteriorly,  $\frac{1}{60}$  inch anteriorly.

Lamina Fusca,—a layer of very fine connective tissue, connecting the sclerotic with the outer surface of the choroid.

Lamina Cribrosa,—the posterior perforated portion of the sclerotic, which at this point is a thin, cribriform lamina. Its largest opening transmits the arteria centralis retinæ.

Arteries,—from the ciliary, are few and in a coarse net-work, the capillaries uniting at long and wide intervals.

Nerves,—from the ciliary, their mode of ending unknown.

The Cornea, or horny body, is the anterior transparent projecting portion of the external tunic of the eyeball, forming about one-sixth thereof. It is set into the sclerotic as a watch-crystal into its case, is of nearly circular base, and its curvature varies in degree in different persons, and in the same person at different ages, becoming flattened in advanced life. It consists of 4 layers,—centrally the true fibrous corneal tissue, having in front the conjunctival epithelium; behind, a homogeneous elastic lamina and the epithelial lining of the anterior chamber. The—

Conjunctival Epithelium,—consists of several layers of epithelial cells, the deepest being columnar, the central polyhedral with processes, and the superficial scaly with flattened nuclei.

Proper Corneal Substance,—a transparent, firm, fibrous structure, continuous with the sclerotic, and composed of about 60 lamellæ of modified connective tissue, superimposed one on the other, and connected by a cement, in which are spaces of stellate shape, each containing a cell, the corneal corpuscle. The anterior layer of the corneal substance was called by Bowman the anterior elastic lamina,

Posterior Elastic Lamina, Membrane of Descemet, or Demours,—is a

structureless basement membrane, of extreme thinness and transparency, the latter being unaffected by water, alcohol or acids; very brittle, exceedingly elastic, and curls up inwardly upon itself, when detached from the true cornea. At the corneal margin it breaks up into fibres, some of which are continuous with the ligamentum pectinatum of the iris.

Fontana's Spaces,—are small, cavernous spaces between the fibres which go to form the ligamentum pectinatum. In some animals, as the ox, they form regular canals. They communicate with the anterior chamber and with the—

Canal of Schlemm, or Sinus Venosus Scleræ,—a minute canal at the internal corneo-sclerotic junction, extending around the circumference of the attached border of the iris. It communicates with the anterior chamber through the spaces of Fontana, also with the scleral veins.

Posterior Epithelial Layer,—a single layer of flattened, polygonal, transparent, nucleated cells, covers the posterior surface of the elastic lamina, lines the anterior chamber and the spaces of Fontana, and is reflected on to the front of the iris.

Vessels,—none, the capillary vessels terminating in loops at its circumference, so that it is practically a non-vascular structure.

Nerves,—are numerous; 24 to 36 twigs from the Ciliary nerves form an intricate plexus throughout its laminated substance.

## THE CHOROID, CILIARY BODY AND IRIS.

The Middle Tunic of the Eye is formed from behind forward by the Choroid, the Ciliary Body and the Iris; the former being the vascular and pigmented tunic; the latter a circular, muscular curtain or septum, with the pupil, an opening in its centre; while the ciliary body connects the choroid with the iris.

The Choroid is a thin, vascular membrane, of dark-brown or chocolate color, which invests the posterior §ths of the globe, extending from the optic nerve entrance behind to the ora serrata of the retina. It is loosely connected externally by the lamina fusca to the sclerotic, the space between being the peri-choroidal lymph-space, and is covered by a thin membrane, the lamina superchoroidea, containing spaces between its constituent lamellæ. Internally it is connected with the pigmentary layer of the retina by the lamina basalis or membrane of Bruch, a very thin, structureless membrane. The Choroid terminates anteriorly in the ciliary processes (see below), and is composed of 2 layers, as follows:—

Lamina Vasculosa, the external layer,—consists chiefly of the venæ

vorticosæ, the larger branches of the short ciliary arteries, and dark pigment cells.

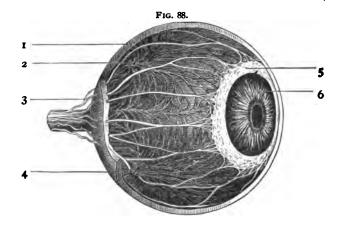

Lamina Chorio-capillaris or Tunica Ruyschiana, the internal layer,—consists of a very fine capillary plexus, formed by the short ciliary vessels.

Tapetum,—is the name applied to the iridescent appearance seen in the outer and posterior part of the choroid of many animals.

Arteries,—are the short ciliary and recurrent branches from the long and anterior ciliary arteries.

Veins (2),—unite into 4 or 5 trunks (4), which pass out through the sclerotic near its equator.

Nerves (3),—are derived from the 3rd, 5th and sympathetic, through the long ciliary and the ciliary branches of the ophthalmic ganglion.

The Ciliary Body (5) comprises the orbiculus ciliaris, the ciliary processes, and the ciliary muscle. It connects the choroid with the circumference of the iris. The—

Orbiculus Ciliaris,—is a zone about ith inch wide, directly continuous with the anterior part of the choroid.

Ciliary Processes,—are 60 to 80 folds, formed by the plaiting of the choroid and its lamina basalis at their anterior margin, and are received into corresponding folds of the suspensory ligament of the lens. They form a sort of plaited frill behind the iris, around the margin of the lens, and are similar in structure to the choroid.

Ciliary Muscle or Muscle of Bowman,—is a ring of unstriped muscular

fibres on the outer surface of the anterior part of the choroid, and consists of radiating and circular fibres. The former arise from the corneo-sclerotic junction and pass backward to the choroid in front of the retina. The circular fibres are internal to the radiating ones have a circular course around the attachment of the iris, and by drawing on the ciliary processes they relax the suspensory ligament of the lens, permitting the lens to become more convex by its own elasticity. It is supplied by the 3rd nerve.

The Iris (6) is a perforated contractile curtain, suspended in the aqueous humor behind the cornea and in front of the lens, and is the anterior portion of the middle tunic of the eyeball, being continuous with the ciliary body and the choroid. It is about  $\frac{1}{6}$  inch wide,  $\frac{1}{160}$  inch thick, and is composed of radiating and circular muscular fibres, a fibrous stroma and pigment cells, covered by a layer of endothelial cells continuous with those of the posterior elastic lamina of the cornea. The—

Pupil,—is the central opening in the iris, situated a little to the nasal side of the centre, diameter  $\frac{1}{12}$  to  $\frac{1}{4}$  inch.

Ligamentum Pectinatum Iridis, or Dollinger's band,—is the suspensory ligament of the iris, connecting its ciliary margin with the posterior elastic lamina of the cornea.

Pars Iridica Retinæ or Uvea,—pigmented epithelium of deep purple color, on the posterior surface of the iris.

Sphincter Pupillæ,—a layer of circular muscular fibres around the pupillary margin, supplied by the 3d nerve.

Dilator Pupillæ,—radiating muscular fibres from the pupillary margin toward the ciliary border, supplied by fibres of the sympathetic from the ciliary ganglion.

Membrana Pupillaris,—a vascular membrane which covers the pupil in the fœtus, disappearing about the eighth month, occasionally permanent.

Arteries,—are derived from the long and anterior ciliary, forming the circulus major at the ciliary border, and the circulus minor near the pupillary margin.

Veins,—empty into those of the ciliary processes and the anterior ciliary veins.

Nerves of the Iris,—are derived from the 3d, 5th and the sympathetic, through the long and short ciliary nerves. The 3d supplies the circular fibres, the sympathetic the radiating ones, the 5th being nerves of common sensation.

#### THE RETINA.

The Retina, the innermost or nervous tunic of the eye, is a delicate, grayish, transparent membrane, about  $\frac{1}{15}$  of an inch thick at the fundus,  $\frac{1}{100}$  inch at the anterior margin. It is formed by a membranous expansion of the optic nerve elements, and extends from the termination of that nerve nearly as far forward as the ciliary processes, terminating in a jagged margin, the ora serrata, though its fibrous stroma is continued as the pars ciliaris retinæ over the ciliary body. The Retina presents for examination the following points;—

Macula Lutea, or Yellow Spot,—situated on the retina, exactly in the visual axis; in an elevated oval spot where vision is very acute, the retina being very thin and full of nerve elements closely packed together at the expense of its connective tissue. No rods, no nerve-fibre layer here, but the cones and ganglion-cells are very numerous.

Fovea Centralis,—a depression at the centre of the macula lutea,  $\frac{1}{125}$  to  $\frac{1}{60}$  inch in diameter, in which the sense of vision is most acute.

Porus Opticus,—the point where the optic nerve enters, lies about \( \frac{1}{8} \) inch internal to the yellow spot. It is often called the blind spot, being the only part of the fundus from which the power of vision is absent.

Colliculus Nervi Optici,—is a slight eminence of the nervous substance at the porus opticus; the central artery of the retina pierces its centre.

Pars Ciliaris Retinæ,—is that portion of the retinal stroma which is prolonged over the ciliary body, and continued over the back of the iris as the pars iridica retinæ. It is destitute of nerve-elements.

Arteries of the Retina,—arise from the arteria centralis retinæ, (branch of the ophthalmic artery), just behind the porus opticus; run chiefly upward and downward, accompanied by veins, to terminate in a minute capillary plexus. They do not anastomose with each other, being terminal arteries. No vessels exist in the fovea centralis, and only the finest capillaries in the macula lutea.

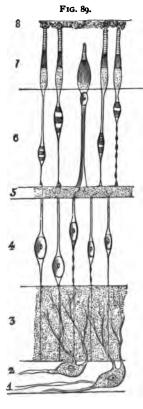

Structure of the Retina. The retina is composed of nervous elements, blood-vessels, pigmented epithelium, and modified connective tissue resembling the neuroglia of the brain; the latter being called the *radiating fibres* or *fibres of Muller*, which form the two limiting membranes and stretch between them, passing through all the nervous layers except Jacob's membrane. The structures are arranged in 10 layers, as follows:—

Membrana Limitans Interna,—derived from the supporting frame-work and shown in the cut by the lowest line.

Layer of Nerve-fibres (1),-formed by the expansion of the optic nerve,

the fibres of which, as simple axis-cylinders, pass through all the succeeding layers of the retina.

Ganglionic Layer (2),—a single layer of large ganglion-cells, which give

ayer of large ganglion-cells, which give off their axons into the preceding layer and their dendrites into the inner molecular layer.

Inner Molecular Layer (3),—is made up of a dense reticulum of minute fibrils, formed by the interlacement of the dendrites of the ganglion-cells with those of the cells of the next layer.

Inner Nuclear Layer (4),—consists of closely packed cells of 3 kinds, bipolar, amacrine, and cells connected with the fibres of Müller.

Outer Molecular Layer (5),—a dense network of minute fibrils derived from the processes of the cells in the adjoining layers.

Outer Nuclear Layer (6),—contains several strata of oval nuclear bodies, named rod-granules and cone-granules, which are respectively continuous with the rods and cones of Jacob's membrane.

Membrana Limitans Externa,—derived from the supporting frame-work of the retina, is shown in the cut by a horizontal line between layers 6 and 7.

Jacob's Membrane, or Layer of Rods and Cones (7),—the perceptive portion of the retina, is composed of a palisadelike arrangement of rods and cones,

the terminal organs probably of the optic nerve fibres.

Pigmentary Layer, or Tapetum Nigrum (8),—formerly described as a part of the choroid, consists of a single layer of hexagonal epithelial cells, loaded with pigment-granules. It extends with the retinal stroma, as the pars ciliaris retina, (see page 255), beyond the ora serrata, where the nervous layers terminate.

#### REFRACTING MEDIA.

The Aqueous Humor is a clear, alkaline, serous fluid, composed of water 96.7, albumen o.r, chloride of sodium and extractive matters 3.2, weighing 4 to 5 grains, and filling the anterior and posterior aqueous chambers, which communicate with each other when the pupil is dilated sufficiently to remove the pupillary margin of the iris from the surface of the lens. The—

Anterior Chamber of the Eyeball,—has the cornea in front and the iri behind.

Posterior Chamber of the Eyeball,—is a narrow chink between the peripheral part of the iris, the suspensory ligament of the lens, and the ciliary processes.

The Vitreous Body is a transparent jelly-like substance, composed of an albuminous fluid enclosed in a delicate membrane, also transparent and named the *hyaloid membrane*. It is apparently structureless, has neither vessels nor nerves, and is situated in the concavity of the retina, which it fills, forming about § of the entire globe. Running antero-posteriorly in its centre is a canal, filled with fluid, and lined by a prolongation of the hyaloid membrane, called the—

Canal of Stilling,—which in the feetus conveyed the hyaloid artery to the membrana pupillaris: (see page 254).

Fossa Patellaris,—is a deep concavity on the front of the vitreous, for the posterior convex surface of the lens.

Hyaloid Membrane,—is the delicate capsule which encloses the vitreous humor, and has been supposed to give off delicate septa into its substance. In front of the ora serrata it is thickened and is termed the—

Zonula Ciliaris or Zonule of Zinn,—presents a series of furrows, radially arranged, for the reception of the ciliary processes. It splits into 2 layers, one of which lines the fossa patellaris, the other is the—

Suspensory Ligament of the Lens,—passes over the ciliary body to be attached to the capsule of the lens.

Canal of Petit,—a sacculated canal, behind the suspensory ligament, encircles the equator of the lens, and lies between the two layers into which the zonule of Zinn is split.

The Crystalline Lens is a bi-convex, elastic, transparent body, enclosed in a capsule, held in place by a suspensory ligament, and situated immediately behind the pupil and in front of the vitreous body, in the fossa patellaris of which its posterior and most convex surface rests. The ciliary processes encircle it and slightly overlap its margin. It consists of concentric layers

formed of minute parallel fibres, which are hexagonal prisms with dentated edges fitting accurately into each other. Faint lines, six or more in number, radiate from the anterior and posterior poles to the circumference and correspond to the free edges of septa in the lens. The external layers are soft, the deeper are firmer, and the central ones form a hard nucleus, the nucleus lentis. The lens is unorganized, having neither vessels nor nerves, but is nourished by imbibition from neighboring structures, possibly from the aqueous humor. Its—

Capsule,—is transparent, elastic,  $\frac{1}{2000}$  inch thick anteriorly,  $\frac{1}{6000}$  inch

posteriorly; has a layer of flat cells between its anterior portion and the lens, which, after death, break down into a fluid, the liquor morgagni.

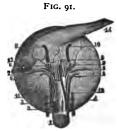

Suspensory Ligament,—connects the capsule with the ciliary body, and is the anterior of the two layers formed by the splitting of the zonule of Zinn (see p. 257). It is shown exaggerated in the cut.

Canal of Petit,—is a triangular space around the circumference of the lens, formed by the separation of the two portions of the zonule of Zinn (shown inflated in the cut).

### MUSCLES AND NERVES OF THE EYEBALL.

Muscles of the Eyeball, are 6 in number, 4 Recti and 2 Oblique, which are inserted into the sclerotic coat, just behind the margin of the cornea. The insertions of the superior, inferior, internal and external recti corre-

spond to the ends of the four arms of an equalarmed cross, imagined to exist behind the corneosclerotic junction. The insertion of the superior oblique (14) lies between the insertions of the superior and external recti, that of the inferior oblique (13) somewhat behind the insertion of the superior oblique. These muscles are described on page 76. The tendon of the superior oblique passes through a pulley or *trochlea* on the internal angular process of the frontal bone, before being inserted into the eyeball: (see Fig. 92).

Nerves supplying the muscles of the eyeball are the 3rd, 4th and 6th cranial nerves; the 3rd supplies the superior, inferior and internal recti and the inferior oblique, the 4th supplies the superior oblique, and the 6th supplies the external rectus.

## VESSELS OF THE EYE.

Arteries supplying the eye and its appendages are,—the Ophthalmic and Anterior Cerebral branches of the internal carotid artery; and the Infraorbital branch of the internal maxillary, from the external carotid. The Ophthalmic Artery arises from the cavernous portion of the internal carotid, enters the optic foramen to the orbit, and gives off the following branches to the eye and its appendages:—

Arteria Centralis Retinæ (2),—pierces the optic nerve (1) obliquely, and is distributed to the retina.

Muscular Branches, 2,—superior and inferior, supply the muscles of the eyeball, and give off the anterior ciliary (see below).

Lachrymal,—to the lachrymal gland, the eyelids, and the conjunctiva, anastomosing with the palpebral.

Supra-orbital,—supplies the superior rectus and levator palpebræ muscles. Palpebral,—superior and inferior,—to the eyelids.

Nasal,-to the lachrymal sac, and the nose.

Short Ciliary, 6 to 12,—pierce the sclerotic at the lamina cribrosa, supplying the choroid and the ciliary processes.

Long Ciliary, 2,—pierce the sclerotic, and pass forward between it and the choroid, to supply the iris, forming two arterial circles thereon, the circulus major at the ciliary border, and the circulus minor near the pupillary margin.

Anterior Ciliary (3),—arise from the muscular branches, form a zone beneath the conjunctiva, then pierce the sclerotic, and join the circulus major on the iris.

Anterior Cerebral, branch of the Internal Carotid,—sends nutrient capillaries to the optic nerve.

Infra-orbital, branch of the Internal Maxillary artery,—sends branches to the inferior rectus and inferior oblique muscles, and to the lachrymal gland.

Veins of the Eye are collected into two main trunks, the Superior and Inferior Ophthalmic Veins, which empty into the cavernous sinus, after collecting the blood from the smaller venous channels through the Venæ Vorticosæ of the choroid. The veins of the eye anastomose freely with the facial veins, thus permitting the escape of venous blood in either direction.

Lymph-spaces of the Eye. The principal lymph-spaces found in the eyeball and its connected structures are the—

Canal of Schlemm,—around the circumference of the iris.

Peri-choroidal Space,—between the choroid and the sclerotic.

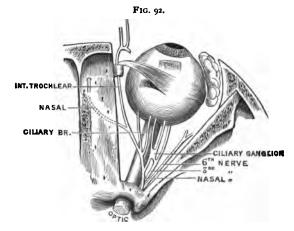

Peri-sclerotic Space,—between the sclerotic and the capsule of Tenon, is continuous with the subdural and subarachnoid spaces.

Vaginal Spaces,—have been described as existing between the sheaths of the optic nerve.

#### NERVES OF THE EYE.

Nerves of the Eye. Besides the 3rd, 4th and 6th nerves, already mentioned as supplying the muscles of the eyeball, the eye is supplied with common sensation by branches from the ophthalmic division of the 5th and the ophthalmic ganglion, also motor filaments from the 5th, and its special sense of sight from the 2nd or optic nerve. The—

Sympathetic Branches,—arise from the medulla, and the cavernous and carotid plexuses, and join the 3rd, 4th, 5th, and 6th nerves, sending filaments to the dilator fibres of the iris, to the muscles of the orbit and lids, to the ophthalmic ganglion, and to the walls of the arteries.

Short Ciliary,—some 6 to 10 in number, arise from the ophthalmic gang lion (see page 198), pierce the sclerotic and go to the ciliary muscle, iris, cornea, and to the sheath of the optic nerve.

Ascending,—from Meckel's ganglion (see page 198), enter the orbit by the spheno-maxillary fissure, going to the optic nerve, the 6th nerve, and the ciliary ganglion.

The Optic Nerve, 2nd Cranial, (Plate 6, page 215), begins at the anterior part of the optic commissure, passes into the orbit by the optic foramen

in company with the ophthalmic artery, is pierced by the central artery of the retina, and enters the eyeball posteriorly  $\frac{1}{6}$  inch inwardly from its axis, piercing the sclerotic and choroid coats, and finally expanding in the retina. It is surrounded by a tubular process of dura mater, which as the nerve enters the orbit, subdivides to form both the sheath of the nerve and the periosteum of the orbit. The two nerves are connected together at the commissure, from the back of which most of their fibres may be traced through the optic tracts to the lower visual centres of the brain, viz.—the external geniculate body, the upper quadrigeminal body, and the pulvinar of the optic thalamus.

The Optic Commissure or Chiasma, (Plate 6, page 215), is seen at the base of the brain in front of the tuber cinereum and behind the lamina cinerea. It contains four sets of fibres, one of which decussates in the commissure with its fellow set of the opposite side. The four sets of fibres are arranged in the following manner:—

Crossed or Decussating Fibres (1),—are the most numerous; lying in the centre of the commissure, they pass from the optic tract of one side to the optic nerve of the other side, connecting the retina of each eye with the opposite hemisphere of the

brain.

Uncrossed or Longitudinal Fibres (2),—occupy the outer sides of the commissure and tracts, passing from the tracts to the nerves of the same sides, and connecting the temporal side of each retina with the cerebral hemisphere of its own side. FIG. 93.

Inter-retinal Fibres (3),—in the anterior portion of the commissure, pass from one optic nerve to the other, connecting the nasal sides of the retinas of both eyes with each other.

Commissural Fibres (4) or Commissure of Gudden,—in the posterior portion of the commissure, have nothing to do with vision, but pass from one internal geniculate body to the other.

The Optic Tract arises from the brain by two bands, an external and an internal. The external band arises from the external geniculate body, the upper quadrigeminal body and the pulvinar of the optic thalamus, the lower visual centres. The internal band arises from the internal geniculate body and the inferior quadrigeminal body, most of its fibres being commissural between the two internal geniculates. The two bands wind around the crus and join together opposite its centre in a flattened band, which becomes cylindrical and continues on to connect with the tract of the opposite side

in the optic commissure. In its course the tract is attached to the surface of the crus by its anterior margin, and receives some fibres from the tuber cinereum and the lamina cinerea.

Meynert's Commissure,—consists of the fibres from the tuber cinereum, which cross in the optic commissure and enter the crus on the opposite side, passing it is said into the subthalamic body, and to the nucleus of the third nerve.

Visual Centres in the Brain. The lower visual centres are the external geniculate body, the upper quadrigeminal body, and the pulvinar of the optic thalamus, to which the optic nerve fibres are traced. From these nuclei other fibres go to the cortical visual centre, which is located in the cuneus of the occipital lobe, and probably also in the adjacent lingual lobule of the temporal lobe.

## APPENDAGES OF THE EYE.

The Tutamina Oculi, or appendages of the eye, include the eyebrows, the eyelids, the conjunctiva, the lachrymal gland, the lachrymal sac, and the nasal duct.

The Eyebrows, or Supercilia, are two arched eminences of thickened integument over the supra-orbital arches, and connected beneath with the orbicularis palpebrarum, corrugator supercilii and occipito-frontalis muscles. They are covered with short, thick hairs, and are drawn downward and inward by the corrugator supercilii: (see page 76).

The Eyelids, or Palpebræ, are two thin, movable folds, placed in front of the eye, for its protection. The upper lid is the more movable one, having its own levator muscle, the levator palpebræ superioris. They are composed externally of skin, internally of mucous membrane (the palpebral conjunctiva), and between these lie areolar tissue, the orbicularis muscle, tarsal cartilage, fibrous membrane, Meibomian glands, vessels and nerves. The upper lid has, in addition, the aponeurosis of the levator palpebræ.

Eyelashes, or Cilia,—are a double or triple row of short hairs, situated on the free margins of the lids; their follicles lying in the connective tissue beneath the tarsal cartilages.

Glands of Moll,—are enlarged and modified sweat-glands, the openings of which are in several rows, near the attachment of the eyelashes.

Palpebral Fissure,—is the space between the free margins of the lids, its outer and inner angles being termed respectively the external and internal canthus.

Lacus Lachrymalis,—is a small triangular space at the internal canthus, between the lids and the globe.

Lachrymal Papilla,—on the edge of each lid, about  $\frac{1}{4}$  inch from the internal canthus.

Punctum Lachrymale,—a minute orifice on each papilla, and the beginning of the lachrymal canal.

Tarsal Plates,—are two, thin, elongated plates of dense connective tissue, about an inch in length, placed one in each lid, giving it form and support. The upper one is crescentic in shape, the lower one is elliptical and smaller.

Tarsal Ligaments, external and internal,—connect the outer angle of the tarsal plate to the malar bone, and the inner angle of the plate to the nasal process of the superior maxilla. The internal one is often called the tendo oculi.

Palpebral Ligaments,—are membranous expansions, one in each lid, attached marginally to the periosteum at the edge of the orbit. Externally the two ligaments fuse to form the external tarsal ligament: (see above).

Meibomian Glands (1),—are sebaceous glands embedded in grooves in the inner surface of the tarsal plates, about 30 in the upper eyelid, less

in the lower one. Their ducts open on the inner edge of the free margin of the lids by minute foramina, through which their secretion is furnished to prevent the lids adhering to each other.

Muscles,—the palpebral portion of the orbicularis muscle is very thin and pale; the tensor tarsi compresses the punctum lachrymale and the lachrymal sac: (see page 76).

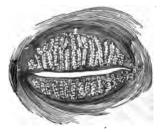

FIG. 94.

Arteries,—are the palpebral branches of

the ophthalmic artery, forming the superior and injerior tarsal arches, and anastomosing with the orbital branch of the temporal, the lachrymal, transverse facial, and angular arteries.

Nerves,—the 3d, facial, and sympathetic to the muscles; the 5th to the skin and conjunctiva.

The Conjunctiva is the mucous membrane lining the inner surface of the eyelids, and reflected over the front of the sclerotic and cornea. It is continuous with the mucous lining of the Meibomian glands, canaliculi, lachrymal sac, nasal duct, lachrymal duct and gland. The—

Palpebral Conjunctiva, -- consists of connective tissue covered by epithe-

lium, is traversed by furrows, and has papillæ, follicular glands, and lymphoid tissue.

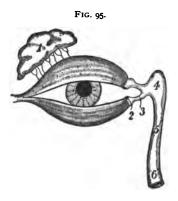

Ocular Conjunctiva,—is very thin and transparent, loosely attached on the sclerotic, firmly adherent over the cornea, where it has no vessels in its structure. It has very few papillæ, and no glands.

Palpebral Folds, superior and inferior,—are where the conjunctiva is reflected over the globe, the fornix conjunctivæ lying between them, and containing mucous glands and trachoma glands, the latter being analogous to lymphoid follicles.

Plica Semilunaris, or Semi-lunar Fold,—a crescentic fold of conjunctiva at the inner canthus, considered to be the rudiment of the membrana nictitans or 3d eyelid of birds.

Caruncula Lachrymalis,—is a small, red, conical body, situated in the lacus lachrymalis, at the inner canthus of the eye; consisting of a small island of skin, containing sebaceous and sweat glands, and a few slender hairs. It is the source of the whitish secretion which collects at the inner angle of the eye. It is connected by tendinous fibres to the capsule of Tenon and to the rectus internus muscle.

The Lachrymal Gland (1) is an oval gland situated in a depression on the orbital portion of the frontal bone, at the outer angle of the orbit, its inferior surface resting on the eyeball, its lower margin or lobe being covered by conjunctiva. Its front portion is separated from the rest of the gland

by a fibrous septum, and is called the accessory gland of Rosenmüller. Its ducts, from 6 to 12 in number, open by a row of orifices on the upper and outer portion of the palpebral conjunctiva. Its secretion, the tears, lubricates the surface of the eyeball; the excess evaporating or being collected in the lacus, from which it passes through the puncta (2) into the canaliculi (3) and the lachrymal sac (4), and thence by the nasal duct (5) to the inferior meatus of the nose.

The Canaliculi (3) or Lachrymal Canals are two minute canals,  $\frac{1}{25}$  inch

in diameter and  $\frac{1}{3}$  inch long, which extend from the punctum (2) in each lid to the lachrymal sac (4). They are lined with mucous membrane, and enveloped by fibres of the tensor tarsi muscle.

The Lachrymal Sac (4) is the superior dilated extremity of the nasal duct (5), and is situated in the groove formed by the lachrymal bone and the nasal process of the superior maxillary. Its form is oval, flattened antero-posteriorly; its dimensions about  $\frac{2}{5}$  inch long and  $\frac{1}{5}$  inch wide. Its fundus is crossed by the tarsal ligament, and by the tensor tarsi muscle. Its junction with the nasal duct may be interrupted by folds of the lining mucous membrane.

The Nasal Duct (5) is a membranous canal extending from the lachrymal sac to the inferior meatus of the nose. It is about  $\frac{3}{4}$  inch long,  $\frac{1}{8}$  inch in diameter, is contained in the osseous lachrymal canal, curving downward, backward and outward, and its calibre is narrowest about its middle. Its mucous lining is thick, and continuous with the Schneiderian membrane of the nasal cavity. The—

Valve of Hasner,—is an imperfect valve at the terminal orifice (6) of the nasal duct, and is formed by a fold of mucous membrane.

## THE EAR.

The Organ of Hearing is divisible into 3 parts—the external ear, the middle ear or tympanum, and the internal ear or labyrinth; which are situated in or upon the mastoid and petrous portions of the temporal bone, (described on page 25): The—

External Ear,—consists of the auricle or pinna, and the auditory canal, which extends to the membrana tympani.

Middle Ear or Tympanum,—consists of the atrium or tympanic cavity proper, and the attic or epitympanic recess; and contains the membrana tympani, the ossicles of the tympanum, and the tympanic orifice of the Eustachian tube.

Internal Ear or Labyrinth,—consists of the osseous labyrinth and the membranous labyrinth, the latter being contained within the former, which comprises the vestibule, the semi-circular canals and the cochlea. The membranous labyrinth consists of the utricle, the saccule and the membranous semicircular canals, and contains the terminal filaments of the auditory nerve.

# THE EXTERNAL EAR.

The Auricle or Pinna is the external irregularly shaped appendage, fastened to the malar and temporal bones by ligaments. It consists of a thin plate of yellow fibro-cartilage, deficient in places where its parts are joined together by fibrous tissue, and is covered by perichondrium and integument, the latter containing sebaceous and sweat glands, and provided

with short, downy hairs. The Auricle presents several elevations and depressions, which are due to the folding of its cartilage, and are named as follows:—

Helix,—the outer curved edge of the pinna, beneath which is a deep groove, the jossa navicularis, or fossa of the helix.

Anti-helix,—a curved ridge, parallel with and in front of the helix, bifurcating above to enclose a triangular depression, the jossa triangularis.

Concha,—the central cavity leading into the auditory canal.

Tragus,—a conical eminence in front of the concha, usually covered with hair along its inferior border.

Anti-tragus,—a smaller projection facing the tragus, from which it is separated by a deep fissure, the incisura intertragica.

Tubercle of Darwin,—a small tubercle frequently seen, where the helix turns downward.

Lobe or Lobule,—the soft, pendulous portion, composed of integumentary, adipose and connective tissues.

Muscles of the Auricle. The extrinsic muscles are the Attollens, Attrahens and Retrahens Auriculam, described on page 76. The intrinsic muscles are very slightly developed, and are the—

Musculus Helicis Major,—vertically on the anterior border of the helix.

Musculus Helicis Minor,—on the lateral surface of the root of the helix.

Tragicus,—lies vertically on the outer surface of the tragus.

Anti-tragicus,—on the posterior wall of the auditory canal.

Transversus Auriculæ,—on the posterior surface of the auricle, radiating outward from the convexity of the concha.

Obliquus Auriculæ,—also on the posterior surface, radiating upward from the convexity of the concha.

The Auditory Canal is an osseo-cartilaginous tube, about 1½ inch long, extending from the concha to the membrana tympani, and curved irregularly in its course. The cartilaginous, or external portion, is about ½ inch long, and deficient posteriorly and above, where it is filled by strong fibrous tissue. The canal is lined with integument, having numerous hair follicles, sebaceous and ceruminous glands. Its relations are—in front, the condyle of the lower jaw; below and in front, the parotid gland; behind, the mastoid cells and the transverse sinus, separated from it by a very thin bony plate; above, the mastoid cells and the dura mater of the brain, separated from it by a thin osseous plate. The—

Sulcus Tympanicus,—is a groove at the bottom of the canal for the insertion of the membrana tympani. It is interrupted above by a notch, the incisura Rivini.

Vessels and Nerves. The Arteries of the auricle are derived from the external carotid artery, viz.—the anterior and posterior auricular, and the auricular branch of the occipital. Those of the auditory canal are branches from the posterior auricular, internal maxillary, and temporal arteries. The Nerves of the canal are derived from the temporo-auricular branch of the inferior maxillary division of the 5th, and the auricular branch of the pneumogastric. Those of the auricle are the—

Auricularis Magnus,-from the cervical plexus.

Auricular,—branch of the pneumogastric (also called Arnold's nerve).

Auriculo-temporal,—branch of the inferior maxillary div. of the 5th.

Occipitalis Major,—from the post. division of the 2nd cervical nerve.

Occipitalis Minor,—from the cervical plexus.

Posterior Auricular,—branch of the facial, to the muscles

#### THE MEMBRANA TYMPANI.

The Membrana Tympani, or Drumhead, is an oval, inelastic, semi-transparent membrane, about  $\frac{1}{250}$  inch in thickness, situated obliquely at the bottom of the auditory canal, inclined inward and forward, so as to form almost a continuation of the posterior wall of the canal. As seen through the canal, it is of a delicate blue-gray color, arched inward, and presents for consideration the following points:—

Tubercle,—white in color at the upper border, made by the short process of the malleus behind.

Stripe,—also white, running downward from the tubercle, and formed by the handle of the malleus behind.

Light-spot,—a triangular reflection, its apex at the tip of the malleushandle, its base extending to the periphery of the membrane. It is due to the concavity of the exterior surface of the membrane.

Umbo, or Navel,—is the dark, central, depressed part of the membrane.

Shrapnell's Membrane,—is the upper posterior part of the drumhead, where it is somewhat flaccid.

Rivinian Foramen,—a minute opening supposed to exist in the portion called Shrapnell's membrane.

Structure. The Membrana Tympani is composed of 3 layers, an external or cuticular layer, a middle or fibrous, and an internal or mucous layer. Its circumference is thickened to form an incomplete ring, which is received into the sulcus tympanicus at the inner end

of the auditory canal. The anterior and posterior ends of this ring are shown by (v) and (h) in the figure. The—

FIG. 96.

External or Cuticular Layer,—is derived from the integument lining the auditory canal.

Middle or Fibrous Layer,—consists of external, radial fibres, which radiate from the handle of the malleus; and internal, circular fibres, most numerous around the circumference. Between these two sets of fibres are situated the short process and handle of the malleus.

Internal or Mucous Layer,—is continuous with the mucous lining of the tympanum.

The Internal Surface of the Membrana Tympani is convex, and presents the curved handle of the *malleus* pointing downward between its layers; also the *chorda tympani* nerve passing along the upper margin to the Glaserian fissure. A fibrous fold descends from the upper portion of the marginal ring, for a short distance along the malleus-handle, forming the—

Anterior and Posterior Pouches,—one on each side of the malleus-handle opening downward.

Fold for the Tensor Tympani Muscle,—containing its tendon, passes downward to the base of the handle of the malleus.

Nerves and Vessels. The Membrana Tympani receives its nervous supply from the auriculo-temporal branch of the inferior maxillary, the auricular branch of the pneumogastric, and the tympanic branch of the glosso-pharyngeal. The Veins open into the external jugular, except those on the inner surface, which drain partly into the lateral sinus and veins of the dura mater, and partly into a plexus on the Eustachian tube. The Arteries are the—

Deep Auricular, branch of the internal maxillary,—supplies the external layer, and forms with the tympanic branches a capillary plexus in the middle layer. (von Trölsch, Roosa, etc.)

Tympanic Branches, of the internal maxillary and internal carotid arteries,—supply the internal layer, the former with the stylo-mastoid artery forming a vascular circle around the membrane, and both anastomosing on the membrane with the—

Vidian,-branch of the internal maxillary, and the-

Stylo-mastoid,—from the posterior auricular branch of the external carotid.

#### THE MIDDLE EAR OR TYMPANUM.

The Tympanum, or *Drum*, is an irregular cavity within the petrous portion of the temporal bone, lying between the membrana tympani and the internal ear, and communicating with the naso-pharynx by the Eustachian tube. It contains the ossicles of the tympanum, part of the chorda tympani nerve, and air. Its average diameters are about ½ inch antero-

posteriorly,  $\frac{1}{3}$  to  $\frac{3}{5}$  inch vertically, and  $\frac{1}{12}$  to  $\frac{1}{3}$  inch transversely. It consists of two parts, the atrium or tympanic cavity proper, opposite the tympanic membrane; and the attic or epitympanic recess above, containing the upper half of the malleus and the greater part of the incus. Its roof and floor are formed by thin osseous laminæ, the floor separating it from the jugular fossa and vein, and presenting, near the inner wall, a small aperture for Jacobson's nerve. The other walls of the tympanum present for examination the following points:—

OUTER WALL,—is formed by the membrana tympani and presents the-

Iter Chordæ Posterius,—opens close to the posterior edge of the drumhead, for the entrance of the chorda tympani nerve.

Iter Chordæ Anterius,—opens just in front of the drumhead, for the exit of the chorda tympani nerve to the canal of Huguier.

Glaserian Fissure,—opens above and in front of the drumhead, receiving the long process of the malleus, the anterior ligament of the malleus, and the tympanic branch of the internal maxillary artery.

INNER WALL,—is the outer wall of the labyrinth, presents the—

Fenestra Ovalis,—an oval opening, leading into the vestibule, and closed by a membrane, to which is attached the base of the stapes.

Fenestra Rotunda,—a smaller opening, below the fenestra ovalis, leading into the scala tympani of the cochlea, and closed by the membrana tympani secundaria, a membrane of 3 layers.

Promontory,—an elevation corresponding to the first turn of the cochlea, situated between the fenestræ and in front of them.

Ridge of the Aquæductus Fallopii,—above the fenestra ovalis, behind which it curves downward along the posterior wall.

POSTERIOR WALL, separates it from the mastoid cells, and presents the—
Opening of the Antrum Mastoideum,—which communicates with the mastoid cells.

Pyramid,—a hollow conical eminence, behind the fenestra ovalis, contains the stapedius muscle, and a minute canal communicating with the aquæductus Fallopii and transmitting a nerve to the stapedius.

Ridge of the Aquæductus Fallopii,—the vertical portion: (see above).

ANTERIOR WALL, separates it from the carotid canal, and presents the-

Opening of Canal for the Tensor Tympani Muscle,—above, situated on a small projection, sometimes called the anterior pyramid.

Opening of the Eustachian Tube,—next below, the two canals being separated from each other by a thin, horizontal, bony plate, the processus cochleariformis.

The Ossicles of the Tympanum are three small bones, which form a

· chain across the tympanic cavity, connecting the membrana tympani with the fenestra ovalis, and named the—

Malleus, or Hammer (A),—consists of a head, neck, short process, long

process or processus gracilis, and handle or manubrium. The short process and handle are fastened to the middle layer of the drumhead. The long process is received into the Glaserian fissure, and the head articulates with the head of the incus.

Incus, or Anvil (B),—has a head, also a long and a short process. The head articulates with the head of the malleus, the short process with the *jossa incudis* in the epi-

tympanic recess, the long process with the head of the stapes, by the os orbiculare, its convex extremity.

Stapes, or Stirrup (C),—presents a head, neck, base and two crura. Its head articulates with the incus, its base rests on the membrane closing the fenestra ovalis, its neck receives the tendon of the stapedius muscle.

Ligaments of the Ossicles are 5 in number, besides the capsular ligaments of their articulations, 3 for the malleus, 1 for the incus, and 1 for the stapes, as follows.

Anterior Ligament of the Malleus,—formerly described as the laxator tympani muscle, from the neck of the malleus to the anterior wall of the tympanum.

Superior of the Malleus,—from the head of the malleus to the roof of the epitympanic recess.

External of the Malleus,—from the short process of the malleus to the posterior part of the notch in the tympanic ring.

Posterior of the Incus,—from the end of the short process of the incus to the posterior part of the epitympanic recess. [The so-called superior ligament of the incus is merely a fold of mucous membrane.]

Annular Ligament of the Stapes,—around the circumference of the base of the stapes, connecting it to the margin of the fenestra ovalis.

Muscles of the Tympanum are 2, the Tensor Tympani and the Stapedius. Formerly two others were described, the laxator tympani and the laxator tympani minor, but the former is now called the anterior ligament of the malleus, and the latter is merely the posterior part of the external ligament of the malleus. The—

Tensor Tympani,—arises from the under surface of the petrous portion of the temporal bone, the cartilaginous Eustachian tube, and its own

osseous canal; and is inserted into the handle of the malleus. It draws the membrana tympani inward and tense. Its *nerve* is a branch from the otic ganglion.

Stapedius,—arises from a conical cavity in the interior of the pyramid; its tendon emerges from the orifice at the apex of the pyramid, and is inserted into the neck of the stapes. It draws the head of the stapes backward, and probably compresses the contents of the vestibule. Its nerve is the tympanic branch of the facial.

Vessels of the Tympanum. The Veins terminate in the pterygoid plexus and in the superior petrosal sinus. The Arteries are 6 in number, as follows:—

Tympanic,—branch of the internal maxillary, entering by the Glaserian fissure, anastomosing on the membrana tympani, in a vascular circle with the Stylo-mastoid and Vidian arteries, and the Tympanic br. of the internal carotid.

Stylo-mastoid,—br. of the posterior auricular br. of the external carotid entering at the stylo-mastoid foramen.

Petrosal,—br. of middle meningeal artery, entering by the hiatus Fallopii. Tympanic,—br. from the internal carotid artery.

Branch from the Vidian,—br. of the internal maxillary; accompanying the Eustachian tube.

Branch from the Ascending Pharyngeal,—from the external carotid; also accompanying the Eustachian tube.

Nerves of the Tympanum. Besides the nerves supplying the two muscles, (see above), the Chorda Tympani Nerve enters the tympanum by the iter chordæ posterius, crosses the cavity between the handle of the malleus and the long process of the incus, and makes its exit by the iter chordæ anterius, after passing close along the upper part of the membrana tympani. The mucous membrane lining the tympanum is supplied by the branches of distribution of the Tympanic Plexus, which lies on the inner wall around the promontory, and is formed by the—

Tympanic Branch of the Glosso-pharyngeal,—also known as Jacobson's nerve, enters by an aperture in the floor near the inner wall.

Small Deep Petrosal,—from the carotid plexus of the sympathetic, enters from the carotid canal.

Small Superficial Petrosal,—from the otic ganglion, enters near the canal for the tensor tympani muscle.

Branch from the Great Superficial Petrosal,—enters through the inner wall, just in front of the fenestra ovalis.

The Eustachian Tube is an osseo-cartilaginous canal, about  $r_{\frac{1}{2}}$  inch long,  $r_{\frac{1}{2}}$  to  $r_{\frac{1}{2}}$  inch in diameter, which forms a channel of communication between the tympanum and the pharynx. It passes obliquely downward, forward and inward, from the anterior wall of the tympanum to the nasopharynx, where it ends in an oval orifice on the side wall of the pharynx just behind the inferior meatus of the nose. The osseous part,  $r_{\frac{1}{2}}$  inch long, terminates at the angle of junction of the petrous and squamous portions of the temporal bone, in a jagged margin, to which the cartilaginous part is attached. The latter,  $r_{\frac{1}{2}}$  inch long, is formed by a triangular plate of elastic fibro-cartilage, folded on itself above so as to leave a deficiency below, which is filled by fibrous tissue. This portion of the tube expands as it descends into a trumpet-shaped lower extremity. The tube is lined by ciliated mucous membrane, continuous with that of the tympanum and pharynx, and containing mucous glands, also adenoid tissue near its lower end. The—

Tube-tonsil,—is formed by the adenoid tissue in the mucous lining near the pharyngeal orifice.

Isthmus,—is the narrowest part of the tube, at the junction of the osseous and cartilaginous portions.

Muscles,—are the dilator tubæ fibres of the tensor palati, which open the tube during deglutition, aided by the salpingo-pharyngeus when present. The levator palati closes the pharyngeal orifice. For these muscles see page 83.

Arteries,—are the ascending pharyngeal, and Vidian, from the external carotid.

Nerves,—are pharyngeal branches from the glosso-pharyngeal, pneumo-gastric and sympathetic, through the pharyngeal plexus, also the upper posterior nasal branches of Meckel's ganglion. The otic ganglion lies on the outer side of the cartilaginous portion of the tube, and supplies the tensor palati muscle.

### THE INTERNAL EAR OR LABYRINTH.

The Internal Ear or Labyrinth is the essential part of the organ of hearing. It lies internal to the tympanum, within the petrous portion of the temporal bone, and consists of a series of osseous chambers, the Osseous Labyrinth, containing a fluid, the perilymph, in which lies a membranous reproduction of the chambers, the Membranous Labyrinth, which also contains a fluid, the endolymph. Within the membranous labyrinth are distributed the terminal filaments of the auditory nerve, which being suspended between two fluids, are not only protected from injury, but enabled to receive the most delicate vibrations communicated to the fluids sur-

rounding them. The Internal Ear comprises the following-named structures:-

Osseous Labyrinth, .... {

Vestibule (4), the central cavity.

Semicircular Canals, behind the vestibule.

Cochlea (8), in front of the vestibule.

(Utricle, a membranous sac, in the vestibule.

Membranous Semicircular Canals, in the osseous canals.

Saccule, a membranous sac, in the vestibule.

Membranous Cochlea, a spiral tube, enclosed in the osseous cochlea.

Auditory Nerve:—the 8th cranial nerve, Portio Mollis of the 7th pair. Organ of Corti,—the terminal auditory apparatus, in the membranous cochlea.

Internal Auditory Meatus,—by which the auditory nerve enters from the brain.

The Vestibule (4) is the central common cavity of communication between the osseous parts of the internal ear, and measures in vertical diameter about  $\frac{1}{5}$  inch, laterally about  $\frac{1}{10}$  inch. It is situated internal to the tympanum, behind the cochlea (8), and in front of the semicircular canals (2), communicating in front with the scala vestibuli of the cochlea, and behind by five openings with the semicircular canals. It contains a fluid, the perilymph, also the utricle and saccule of the

membranous labyrinth, and presents the following points:-

Fenestra Ovalis,—on its outer wall, closed by the base of the stapes and its annular ligament.

Fovea Hemisphærica (7),-a small circular depression on the inner wall, for the saccule, perforated by several minute orifices for filaments of the auditory nerve.

Crista Vestibuli,—a vertical ridge on the inner wall behind the fovea. It bifurcates below to enclose the-

Digitized by Google

Fossa Cochlearis,—a small depression, perforated for the passage of filaments of the auditory nerve.

Aquaductus Vestibuli,—opens behind the crista, ending on the posterior surface of the petrous portion of the temporal bone. It transmits a small vein, and contains the ductus endo-lymphaticus, a tubular prolonga-

18

tion of the lining membrane of the vestibule, which ends in a cul-desac between the layers of the dura mater in the cranial cavity.

Fovea Semi-elliptica (6),—a transverse oval depression on the roof; behind it are the 5 orifices of the semicircular canals, and in front is the opening into the scala vestibuli of the cochlea.

The Semicircular Canals are three C-shaped bony tubes, each about  $\frac{1}{20}$  inch in diameter, situated above and behind the vestibule, into which they open by 5 apertures. Each canal lies at a right angle with the other two. The superior and posterior canals are each nearly an inch long, and are placed vertically; they join together behind in the crus commune, which opens into the vestibule. The external canal is about  $\frac{1}{6}$  inch long, placed horizontally, its arch being directed outward and backward. The canals contain the perilymph, and the membranous semicircular canals. The—

Ampulla,—is a flask-shaped dilatation of each canal at one extremity, having a diameter of about  $r_0^1$  inch.

The Cochlea is a bony tube, about  $1\frac{1}{2}$  inch long, tapering from 10 to  $\frac{1}{20}$  inch in diameter, coiled around a central conical axis for  $2\frac{3}{4}$  turns, and resembling a snail-shell in appearance; is situated in front of the vestibule, its apex pointing forward and outward, and is separated from the carotid canal in front by a thin wall. Its central axis, the *modiolus*, is of conical shape, and is channeled by small canals for the passage of arteries and nerves, and by a central one, the *canalis centralis modioli*. Its apex is

within the last coil of the cochlea, and is expanded into a funnel-shaped lamella, the infundibulum. The—

Canalis Spiralis Modioli, or Spiral Canal,—is the space between the modiolus and the outer wall of the cochlea. It makes 23 turns, from left to right in the right ear, from right to left in the left ear; and ter-

minates in the *cupola*, a cul-de-sac at the apex of the cochlea. It presents 3 openings,—the *jenestra rotunda* (see page 269), communicating with the tympanum; the opening into the vestibule, and the orifice of the aquæductus cochleæ (see below).

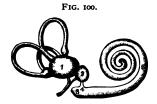

Lamina Spiralis (b),—is a thin, osseous plate, projecting from the modiolus half way across the spiral canal, and winding around the modiolus terminates near the apex in a hook-like process, the hamulus. Its deficiency in the last half turn of the cochlea forms the Helicotrema, a space in which the two scalæ unite. It consists of two laminæ,

between which pass the filaments of the cochlear nerve. From its free edge the structures composing the membranous cochlea pass to their attachment on the opposite wall of the cavity. It partially divides the spiral canal into 2 passages, the scala vestibuli above and the scala tympani below.

Aquæductus Cochleæ,—is a minute funnel-shaped canal which begins by a small orifice in the lower wall of the scala tympani, and runs in the inner wall of the jugular fossa, ending on the basilar surface of the petrous portion of the temporal bone. It transmits a vein from the cochlea to the jugular vein, and forms a communication between the perilymph in the scala tympani and the subarachnoidean space of the brain.

. The Membranous Labyrinth is situated within the osseous labyrinth, and consists of two membranous sacs, the *Utricle* (1) and *Saccule* (2), which

lie in the vestibule, together with the Membranous Semicircular Canals (6), and the Membranous Cochlea (5). The utricle and saccule communicate with each other indirectly by a small canal contained in the aquæductus vestibuli. The saccule communicates with the membranous cochlea by the canalis reuniens (4), and the membranous semicircular canals open into the utricle; so that the membranous laby-

rinth affords an uninterrupted channel for the *endolymph* which it contains. The walls consist of 3 layers,—an outer fibrous coat, a middle one resembling the hyaloid membrane, and an inner layer, formed of polygonal, nucleated epithelial cells. In the walls of the utricle and saccule are contained 2 small bodies, the—

Otoliths,—consisting of minute crystals of calcium carbonate, held together in a mesh of delicate fibrous tissue.

The Utricle (1) is a flattened, oblong membranous sac, fastened to the inner wall of the vestibule in the fovea semi-elliptica. It is filled with endolymph, nearly surrounded by perilymph, and communicates with the saccule through the small tube in the aquæductus vestibuli. The membranous semicircular canals open into its cavity behind by 5 orifices. The—

Macula Acustica Utricularis,—is a thickened spot in the wall where it is lodged in the fovea, receiving the utricular filaments of the auditory nerve.

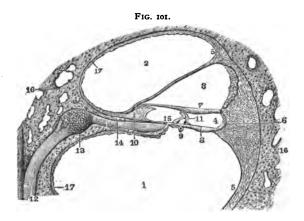

Ductus Endolymphaticus,—is given off from the anterior wall, through the aquæductus vestibuli, to the cavity of the saccule.

The Saccule (2) is the smallest of the two membranous sacs, about \( \frac{1}{3} \) inch in diameter, attached at one point to the utricle, and also to the fovea hemispherica of the vestibule, being elsewhere surrounded by perilymph, and containing endolymph. It communicates with the utricle through the ductus endolymphaticus in the aquæductus vestibuli, and also with the membranous cochlea by its neck, the—

Canalis Reuniens (4),—about  $\frac{1}{15}$  inch long and  $\frac{1}{120}$  inch in diameter, connects the cavity of the saccule and the vestibular end of the membranous cochlea (3).

Macula Saccularis,—is a dense, circular point,  $\frac{1}{12}$  inch in diameter, on the wall of the saccule, formed by a thickening of the connective tissue where the saccular filaments of the auditory nerve enter.

The Membranous Semicircular Canals have the same shape as the osseous ones in which they are contained but are  $\frac{1}{3}$  their diameter. They are fastened thereto by the convex curves, and are elsewhere surrounded by perilymph, except at the ampullary enlargements, where they fill the osseous canals and present a thickened elevation projecting into the cavity and called the septum transversum, in which the nerves end. They are held in position by numerous fibrous bands, connecting them to the walls of the osseous canals.

The Membranous Cochlea, also called the *Ductus Cochlearis* or *Scala Media*, is a spiral tube enclosed in the spiral canal of the osseous cochlea (16), lying along its outer wall, to which it is attached, being also attached to the lamina spiralis (10) on the opposite side of the cavity. It is formed

by the membrana basilaris (8) below, the membrane of Reissner (18) above, and the periosteum of the cochlear wall on the outer side, its cross-section being of triangular form. It is filled with endolymph, and contains the organ of Corti (11) covered by the membrana tectoria (7). The—

Limbus Laminæ Spiralis (10),—is the soft structure of periosteum on the edge of the lamina spiralis, and lies in the membranous cochlea. It has two lips,—an upper, the labium vestibulare, and a lower, the labium tympanicum, with a C-shaped concavity, the sulcus spiralis internus, between them.

Membrane of Reissner (18),—extends from the edge of the lamina spiralis to the outer cochlear wall, separating the membranous cochlea from the scala vestibuli (2).

Membrana Basilaris (8),—is the tympanic wall of the membranous cochlea, extending from the labium tympanicum of the lamina spiralis to the outer cochlear wall, where its insertion is called the ligamentum spirale (5), or muscle of Todd and Bowman. On it rests the Organ of Corti (11),—covered by the membrana tectoria.

Membrana Tectoria (7),—extends parallel to the membrana basilaris from the labium vestibulare, over the organ of Corti, to be attached externally to the outer row of Deiters' cells (see below).

Vas Spirale (9),—a vessel in the vascular connective tissue of the membrana basilaris, below the organ of Corti.

Zona Arctuata,—is the inner area, and the zona pectinate is the outer area, of the membrana basilaris.

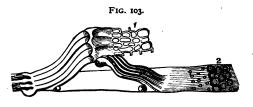

The Organ of Corti (11), or Papilla Spiralis, is situated on the inner surface of the membrana basilaris (8), is covered by the membrana tectoria (7), and appears as a papilla winding spirally throughout the length of the membranous cochlea. It is an arrangement of cells, some of which are rod-like in form, and others are epithelial hair-cells, the whole being supposed to be the essential organ of hearing. The—

Rods of Corti,—are arranged in two rows, resting, by their pedestals, on the membrana basilaris, and uniting with each other by their heads, so as to form an arched tunnel, the tunnel of Corti, between them and the membrana basilaris all along the length of the cochlea. Number of rods in inner row about 6,000, in outer row 4,000. Average diameter of the rods, from \$35000 to \$35000 inch.

FIG. 102.

Head plates,—are attached to the heads of the inner rods, for the reception of the rods of the opposite row.

Lamina Reticularis (1),—a delicate perforated membrane which extends

from the articulations of the rods outwards to the external row of the outer hair-cells.

Auditory Cells (2),—are epithelial structures covering the inner surfaces of the walls and the floor of the

membranous cochlea. Those which cover the inner rods by a single row number about 3,500, are nucleated, covered with tufts of cilia, and called the *inner hair-cells*. On the outer rods are 3 or 4 rows of similar cells, numbering about 12,000, and named the *outer hair-cells*. Between the latter are rows of supporting cells, called the *cells of Deiters*, and outside them are 5 or 6 rows of columnar cells, the *cells of Hensen*, beyond which are the *cells of Claudius*.

The Auditory Nerve, the 8th or Portio Mollis of the 7th pair, arises by two roots from the medulla oblongata, the vestibular root from the trigonum acustici in the floor of the 4th ventricle, the cochlear root from the accessory nucleus and the tuberculum acusticum, in the medulla, close to the restiform body. It emerges from the medulla at the lower border of the pons Varolii, in company with the facial nerve, from which it receives one or two filaments, both nerves passing into the internal auditory meatus, at the bottom of which the auditory divides into two branches, vestibular and cochlear. The—

Vestibular Nerve,—has a ganglion, the ganglion of Scarpa, on it in the internal auditory meatus; it then divides into 3 branches, which pass through minute orifices in the bottom of the meatus, and entering the vestibule, are distributed to the utricle and the ampullæ of the external and superior semicircular canals respectively.

Cochlear Nerve,—gives off branches to the saccule and the ampulla of the posterior semicircular canal, and then divides at the base of the modiolus of the cochlea into numerous filaments (14), which pass between the lamellæ of the lamina spiralis to the hair-cells of the organ of Corti (Fig. 101). On it in the spiral canal of the modiolus is the—

Ganglion Spirale (13),—consisting of bipolar nerve-cells, which are the true cells of origin of this nerve, one pole being prolonged centrally to the brain, and the other peripherally to the hair-cells of Corti's organ.

The Internal Auditory Meatus is a large orifice on the posterior surface of the petrous portion of the temporal bone, leading into a short canal, which runs outward for  $\frac{1}{3}$  inch, and is closed by a vertical plate, the *lamina cribrosa*, divided by a crest, the *crista falciformis*, into 4 depressions, which are perforated by foramina for the passage of the branches of the auditory nerve into the labyrinth. The—

Tractus Spiralis Foraminosus,—is the anterior lower depression; has a number of foramina spirally arranged and opening into the central canal of the cochlea, transmitting the nerve to the cochlea.

Area Cribrosa Media,—just below the posterior part of the crest, transmits the nerves to the saccule.

Foramen Singulare,—behind the preceding area, for the nerve to the posterior semicircular canal.

Area Cribrosa Superior,—above the crest posteriorly, for the filaments to the utricle and the superior and external semicircular canals.

Opening of the Aquæductus Fallopii,—above and in front, for the passage of the facial nerve.

Opening of the Aquæductus Vestibuli,—a slit behind the meatus, transmits the ductus endolymphaticus, also a small artery and vein.

Vessels of the Internal Ear. The Veins accompany the arteries, and uniting at the base of the modiolus empty into the superior petrosal sinus or into the lateral sinus. The Arteries are the—

Internal Auditory, br. of the basilar (from the vertebral),—accompanies the auditory nerve into the internal auditory meatus, where it divides into vestibular and cochlear branches.

Stylo-mastoid, br. of the posterior auricular (from the external carotid),—sends some small branches to the internal ear.

# ORGANS OF DIGESTION.

The Alimentary Canal is a musculo-membranous tube, about 30 feet in length, extending from the mouth to the anus, lined throughout with mucous membrane, furnished with several accessory organs, and performing the functions of ingestion, mastication, insalivation, deglutition, digestion, assimilation, and egestion. Its subdivisions are named the—Mouth, Pharynx, Œsophagus, Stomach, Small Intestine (duodénum, jejúnum and ileum) and Large Intestine (cæcum, colon and rectum). The first three lie above the diaphragm, the rest below it.

Accessory Organs of Digestion are the—Teeth, Salivary glands (parotid, sub-maxillary, sub-lingual), Liver, Pancreas, and Spleen.

## THE MOUTH.

The Mouth is an oval-shaped cavity, placed at the commencement of the alimentary canal, and consists of the vestibule, and the cavity proper. The vestibule is a slit-like aperture between the lips and cheeks in front and the gums and teeth behind. The cavity proper extends from the alveolar arches and their teeth in front and laterally to the isthmus of the fauces behind, by which constricted aperture it communicates with the pharynx. Its roof is formed by the palate, its floor by the tongue and its mucous membrane reflected to the lower gum. The lips are the two fleshy folds, which surround the orifice of the mouth, the cheeks forming its sides and being continuous with the lips in front; both are formed of skin externally, and mucous membrane internally; between which are muscle, fat, areolar tissue, vessels, nerves and glands. The mouth presents for examination the tongue (see page 243), the gums and teeth (described separately), the palate, fauces, tonsils, and openings of ducts from the salivary glands. Special anatomical features presented by the mouth are the—

Hamular Process of the Sphenoid Bone,—may be felt behind the last upper molar tooth; also the internal pterygoid plate, and part of the pterygoid jossa.

Coronoid Process,—of the lower jaw, at its anterior border.

Posterior Palatine Artery,—at the inner side of the last upper molar tooth, and in front of the hamular process.

Pterygo-maxillary Ligament,—is felt as a fold posteriorly to the last lower molar tooth.

Lingual Branch of the 5th,—the gustatory nerve,—passes over the inner side of the ramus of the lower jaw, close to the last lower molar tooth.

Openings of Stenson's Ducts, from the parotid glands,—in the vestibule, one on each cheek, opposite the 2nd upper molar tooth.

Openings of Wharton's Ducts, from the submaxillary glands,—in the cavity proper, one on each side of the frænum of the tongue.

Openings of the Ducts of Rivinus, from the sublingual glands,—8 to 20 on each side, open into the cavity proper, on either side of the frænum of the tongue.

# THE PALATE AND TONSILS.

The Palate forms the roof of the mouth, and consists of the hard palate in front, and the soft palate behind. The *Hard Palate* is formed by the palate process of the superior maxillary bone and the horizontal plate of the palate bone, is covered with mucous membrane, which is closely adherent the periosteum, and presents along the median line, a linear ridge or

raphé, which terminates anteriorly in a papilla corresponding to the inferior opening of the anterior palatine fossa. The Soft Palate is a movable fold suspended from the posterior border of the hard palate, and forming an incomplete septum between the mouth and the pharynx. It consists of a fold of mucous membrane, enclosing muscular fibres, an aponeurosis, adenoid tissue, vessels, nerves and mucous glands; and is formed by fibres of the following—

Muscles, 5 on each side, the—levator palati, tensor palati, palato-glossus, palato-pharyngeus, and the azygos uvulæ;—the latter forming with its fellow the—

Uvula,—a conical-shaped, pendulous process, which hangs down from the middle of the free border of the soft palate.

Anterior Pillars of the Fauces,—arch downward and forward to the base of the tongue, and contain the palato-glossi muscles.

Posterior Pillars of the Fauces,—arch downward and backward to the sides of the pharynx, and contain the palato-pharyngei muscles.

Isthmus Faucium,—the space bounded by the pillars of both sides, the free border of the palate, and the base of the tongue. It communicates with the mouth anteriorly and with the pharynx posteriorly.

The Tonsils, or Amygdalæ, are two prominent bodies, situated one on each side, between the anterior and posterior pillars of the fauces, and nearly an inch in front of the internal carotid artery. Their inner surfaces show 12 to 15 orifices, leading into recesses, from which follicles branch out into the substance of the gland. The follicles are numerous, and are surrounded by a layer of closed capsules of adenoid tissue, and a plexus of lymphatic vessels communicating with the deep cervical glands. The—

Fossa Supra-tonsillaris,—is a recess above the tonsil, and is covered by the plica semilunaris, a fold of mucous membrane.

Arteries are—the dorsalis linguæ, from the lingual; the ascending palatine and tonsillar, from the facial; the ascending pharyngeal, from the external carotid; the descending palatine, from the internal maxillary; and a twig from the small meningeal.

Veins,—terminate in the tonsillar plexus, situated on the outer side of the tonsil.

Nerves,—are derived from the spheno-palatine ganglion, and from the glosso-pharyngeal.

# THE SALIVARY GLANDS.

The Salivary Glands, communicating with the mouth, are the Parolad, the Submaxillary, and the Sublingual glands. They are compound, racmose glands, consisting of numerous lobes, made up of smaller lobules

Digitized by GOOGLE

connected together by dense areolar tissue, vessels and ducts. Each lobule consists of the ramifications of a duct, the branches terminating in dilated ends or alveoli, on which the capillaries are distributed, and which are enclosed by a reticulated basement membrane. The alveoli are lined by cells, which secrete a mucous secretion in the sublingual gland, or a serous fluid in the parotid gland; the submaxillary producing both kinds. Mucous Glands are also found in the mouth, in the tongue, the tonsil, and the soft palate.

The Parotid Gland (1) is the largest of the three salivary glands, and weighs from ½ oz. to 1 oz. It lies upon the side of the face, below and in front of the externalear, and pas ses over the masseter muscle anteriorly, and into the back part of the glenoid fossa, behind the articulation of the lower jaw. Passing through it are the following—

Structures,—the external carotid artery and its terminal branches, the posterior auricular, temporal, and internal maxillary; the vein formed by the union of the temporal and internal maxillary veins, the facial nerve and its branches, branches of the great auricular nerve, and the auricular-temporal branch of the inferior maxillary nerve. The internal carotid artery and the internal jugular vein lie close to its deep surface.

Stenson's Duct (2),—is the duct of the parotid gland, and is about 21/2

inches long. It begins by numerous branches from the anterior part of the gland, crosses the masseter muscle, pierces the buccinator, and opens on the inner surface of the cheek by a small orifice opposite the 2nd molar tooth of the upper jaw.

Socia Parotidis,—is a small, detached portion of the gland, which occasionally exists as a separate lobe, just beneath the zygomatic arch. Its duct

empties into Stenson's duct, where the latter crosses the masseter muscle.

Arteries,—are derived from the external carotid.

Veins,—empty into tributaries of the external jugular.

Lymphatics,—terminate in the superficial and deep cervical glands.

Nerves,—are derived from the carotid plexus of the sympathetic, the facial, auriculo-temporal and great auricular nerves.

The Submaxillary Gland (3) lies below the jaw, in the anterior part of the submaxillary triangle, and upon the mylo-hyoid, hyo-glossus, and stylo-glossus muscles, the facial artery lying embedded in a groove in its upper, posterior border. Its duct—

Wharton's Duct (4),—is about 2 inches long, and opens on the summit of a papilla at the side of the frænum of the tongue.

Arteries,—are branches of the facial and the lingual; the veins following the course of the arteries.

Nerves,—are branches of the submaxillary ganglion, and are derived through the ganglion from the chorda tympani, the lingual, and the sympathetic.

The Sublingual Gland (5) is the smallest of the salivary glands, and is situated beneath the mucous lining of the floor of the mouth, at the side of the frænum of the tongue, and in contact with the inner surface of the lower jaw. Its ducts, the—

Ducts of Rivinus,—from 8 to 20 in number; some join Wharton's duct, others open on the side of the frænum linguæ.

Duct of Bartholin,—is a tube formed by one or more of the preceding ducts; it opens into Wharton's duct.

Arteries,—are derived from the sublingual and submental.

Nerves,—are branches from the lingual nerve.

## THE TEETH.

The Teeth are 32 organs of digestion, situated 16 in each jew, where they are implanted within the alveoli, and are partly surrounded by the gums. In each half of each jaw there are—

Temporary Teeth (5)—2 Incisors, 1 Canine, 2 Milk-molars.

Permanent Teeth (8)—2 Incisors, 1 Canine, 2 Bicuspids, 3 Molars.

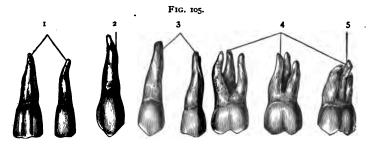

The Gums are composed of dense fibrous tissue, closely connected to the periosteum of the alveolar processes, and surrounding the necks of the teeth. They are covered with mucous membrane, presenting numerous fine papillæ around the dental margin, and reflected into the alveoli, where it is continuous with the periosteal lining membrane.

Characteristics of the Teeth. Each tooth consists of a—crown or body, projecting above the gum; root or jang, embedded within the alveolus; and the neck, the constricted portion between the crown and the fang. The roots are entirely concealed within their alveoli, and are covered by the

pericementum, a reflection of the periosteum lining the alveoli, which becomes continuous with the fibrous structure of the gums. The pulp-cavity occupies the centre of the tooth, opening at the apex of the fang for the passage of vessels and nerves to the pulp. Each class of teeth presents the following characteristics:—

Incisors, or Cutters (1),—Crown chisel-shaped, beveled posteriorly. Fang single, long, thickest antero-posteriorly.

Canines, or Tearers (2),—Crown thick and conical. Fang longest and

thickest of all the teeth, forming a projection on the alveolar arch. The 2 upper canines are the "eye-teeth."

Bicuspids (3),—Crown has 2 cusps. Fang single but grooved deeply, showing a marked tendency to bifurcate.

Molars, or Grinders (4),—Crown large, low and cuboid in shape, has 4 cusps on upper molars, 5 on the lower ones. Fangs multiple, usually 3 on the first two upper molars, 2 on the first two lower ones. The third molar (5) is called the "wisdom-tooth," from its late eruption; its fangs are usually fused together into a grooved cone.

Structure of the Teeth. A tooth consists of 3 structures,—the dentine, the proper dental substance, forming the larger portion; the enamel, a layer covering the crown; and the cement, a thin layer on the surface of the fang. A central chamber, the pulp-cavity, occupies the interior, and contains the pulp, a soft, vascular, and sensitive organ, surrounded by a layer of cells, the odonto-blasts or dentine-forming cells. The—

Pulp-cavity,—has a process extending down each root, and opening at the apex by a minute orifice, which transmits vessels and nerves to the pulp.

Pulp,—is made up of myxomatous tissue, and contains numerous blood-vessels and nerves, but no lymphatics.

Dentine, or Ivory (2),—consists of tubules surrounded by the inter-tubular

tissue or matrix, and opening into the pulp cavity. It resembles com-

pact bone in appearance and in composition, consisting of 28 parts animal matter and 72 earthy matter.

Dentinal Tubui,—in the dentine, are delicate, wavy canals, diameter about 43000 of an inch, which branch outwardly and anastomose with each other, forming concentric shadings called Schreger's lines. They contain slender prolongations from the processes of the cells of the pulp-tissue.

Enamel (3),—covers the crown; consists of very dense tissue, containing but 3½ per cent. of animal matter. Its earthy matter, 96½ per cent., is composed chiefly of the phosphate and carbonate of calcium. It is covered by a delicate epithelial cuticle, Nasmyth's Membrane, which when intact withstands the action of acids.

Crusta Petrosa, or Cement (1),—the enamel of the fang; is a thin layer of true bony tissue, containing lacunæ, canaliculi, and occasionally Haversian canals.

Development of the Teeth. The teeth are evolved from the dermoid system, not from the skeleton. They are developed from two of the primitive layers of the embryo,—the epiblast

FIG. 106.

producing the enamel, and the mesoblast giving rise to the dentine, pulp, cement, and pericementum. About the 7th week of feetal life, two parallel ridges arise along the summit of each jaw, and a corresponding epithelial lamina sinks into the mesoblastic tissue beneath. This lamina sends off 10 cords, one for each tooth, from its inner edge; the cords expand into flask-like forms, and gradually assume the forms of the teeth, constituting their enamel-organs. They meet and enclose papillæ, which arise from the mesoblastic tissue, forming a series of sacs, which with their contents are the dental follicles, having fibrous septa between them. In each follicle the vascular papilla has on its surface a layer of cells, named odontoblasts, from which the dentine is developed by calcification, the remainder of the papilla forming the pulp of the tooth. The cement is produced later by the tissue of the dental sac, in the same manner as bone is produced by periosteum.

When calcification has advanced sufficiently, the pressure of the teeth causes the absorption of the gum above them, the teeth erupt, and the fibrous septa ossify, forming the alveoli, which embrace the necks of the teeth in a firm hold.

The 10 permanent teeth, which replace the temporary ones in each jaw, are developed from special germs (enamel-organs) which arise from the lamina behind the germs for the temporary teeth, and recede into the tissue, to enclose mesoblastic papillæ, and go through the same process as described for the temporary teeth. These germs appear about the 16th week. The 6 superadded permanent teeth arise from successive backward extensions of the lamina, projected from the back of that for each preceding tooth, and thus forming a special dental germ for each added tooth.

Eruption of the Teeth. The temporary teeth begin to appear through the gum at the 7th month after birth, the lower central incisors appearing first. Their eruption ends with the appearance of the second molars, about the age of two years. The lower teeth slightly antedate the upper. Their formula is as follows:—

$$\begin{cases} &\text{Mo. Mo. Ca. In. In. In. In. Ca. Mo. Mo.} \\ &\frac{\text{Upper ... } \quad \text{I} \quad \quad \frac{1}{1} = 10} \\ &\frac{1}{\text{Lower ... } \quad \frac{1}{1} \quad \frac{1}{1} \quad \frac{1}{1} \quad \frac{1}{1} \quad \frac{1}{1} \quad \frac{1}{1} = 10} \end{cases} = 20.$$

Of the permanent teeth, the first molars appear about the end of the 6th year, followed by the incisors about the 7th or 8th year, the bicuspids from the 9th to the 10th year, the canines about the 11th or 12th year, the second molars from the 12th to the 13th year, and the third molars from the 17th to the 21st year. Those of the lower jaw are slightly in advance of the corresponding upper ones Their formula is as follows:—

The greatest number of teeth at one time in the jaws is 48,—including all the temporary and permanent teeth except the third molars, if none have been lost. This occurs between the 5th and 7th years of age.

## THE PHARYNX.

The Pharynx is a conical, musculo-membranous tube, about 4½ inches long, hung base up from the basilar process of the occipital bone, and extending to the lower border of the cricoid cartilage posteriorly, or the 5th cervical vertebra, where it becomes continuous with the œsophagus (5). It forms that part of the alimentary canal which lies behind the mouth, being

incomplete in front where it opens into that cavity. From above downward it may be divided into—the naso-pharynx, above the level of the soft palate; the oral part, between the levels of the soft palate and the hyoid bone; and the laryngeal part, below the latter level. It is connected with—

Anteriorly,—the internal pterygoid plate, pterygo-maxillary ligament lower jaw, base of the tongue, cornua of the hyoid bone, stylo-hyoid

ligament, thyroid and cricoid cartilages

of the larvnx.

Posteriorly,—the longus colli and recti capitis antici muscles, and by loose areolar tissue to the first 5 cervical vertebræ.

Laterally,-the styloid processes and their muscles, and is in contact with the common and internal carotid arteries, the internal jugular vein, the 9th, 10th, 12th and sympathetic nerves, and above with a small part of the internal pterygoid muscles.

Above,-it is limited by the body of the sphenoid bone, and the basilar process of the occipital bone.

Openings into the Pharynx,—are 7 in number; the 2 posterior nares, the 2 Eustachian tubes, the mouth, the larynx and the œsophagus.

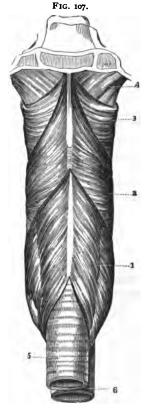

The Naso-pharynx is that portion of the pharynx lying behind the nose and above the level of the soft palate. Its cavity, unlike the rest of the pharynx, always remains open. The-

Eustachian Tube,—opens on its lateral wall, by a cleft-like orifice, behind the inferior meatus of the nose, and just above the level of the floor of the nasal fossa.

Pharyngeal Tonsil,—a mass of lymphoid tissue, in the back wall of the pharynx, between the two Eustachian tubes.

Bursa Pharyngea,—an irregular depression of the mucous membrane in the middle line of the pharynx, above the pharyngeal tonsil.

Cushion or Tubal Prominence,—immediately behind the orifice of the

Eustachian tube, due to the pressure of the extremity of the cartilage of the tube.

Fossa of Rosenmüller,—a deep recess, behind the cushion.

Structure of the Pharynx. The pharynx is composed of 3 coats,—a mucous, a muscular and a fibrous, the latter lying between the other two, and called the *pharyngeal aponeurosis* (4). The mucous coat is covered with ciliated columnar epithelium above the level of the floor of the nares—below that level with squamous epithelium; and contains racemose mucous glands, especially around the orifices of the Eustachian tubes, also numerous crypts or recesses, surrounded by lymphoid tissue. The—

Pharyngeal Aponeurosis (4),—is thick above, where it is firmly attached to the basilar process of the occipital bone, and the petrous portion of the temporal bone. Posteriorly it presents a fibrous band or raphé in the median line, which gives attachment to the constrictor muscles.

Muscles,—are the inferior (1), middle (2), and superior (3) constrictors of the pharynx, the stylo-pharyngeus and the palato-pharyngeus, which have been described on page 82.

Vessels and Nerves. The Arteries of the pharynx are the superior thyroid and ascending pharyngeal, also the pterygo-palatine and descending palatine branches of the internal maxillary; all from the external carotid. The nerves are branches from the—

Pharyngeal Plexus,—formed by the pharyngeal branches of the pneumogastric, glosso-pharyngeal, external br. of the superior laryngeal, and superior cervical ganglion of the sympathetic.

# THE ŒSOPHAGUS.

The Œsophagus is a musculo-membranous tube, about 9 inches long, extending from the 5th cervical vertebra and the upper border of the cricoid cartilage of the larynx, through the œsophageal opening in the diaphragm to the cardiac orifice of the stomach, where it terminates opposite the 10th dorsal vertebra. In the neck it lies between the trachea and the vertebral column, resting in part on the longus colli muscle; then inclining to the left side it reaches the posterior mediastinum behind the left bronchus, and descends in that mediastinum, at first in front of the thoracic duct, lower down to its left. The Œsophagus is composed of 3 coats, as follows:—

Muscular Coat,—has longitudinal fibres externally, circular fibres internally, which are continuous with the fibres of the stomach below, and with those of the inferior constrictor muscle above.

Areolar Coat,—forms a loose connection between the other two coats, and contains the œsophageal vessels.

Mucous Coat,—in thick longitudinal folds, covered with a layer of stratified pavement epithelium.

Esophageal Glands,—are compound racemose glands, situated in the submucous tissue throughout the tube, but most numerous at the lower end, close to the cardiac orifice of the stomach.

Arteries,—are chiefly branches from the thoracic aorta.

Veins,—empty into the vena azygos minor.

Nerves,—are branches from the asophageal plexus, which is formed by branches from the pneumogastric and the cervical sympathetic.

## THE ABDOMEN.

The Abdomen is a large, oval-shaped cavity, situated between the thorax above and the pelvis below, and Bounded-above, by the diaphragm; below, by the brim of the pelvis; posteriorly, by the vertebral column, and the fasciæ covering the psoæ and quadrati lumborum muscles; anteriorly and laterally, by the transversalis fascia, the lower ribs and the venter of the ilium. It is invested internally by the Peritoneum, and it contains the-

Stomach.	Pancreas.	Abdominal Aorta.
Intestines.	Kidneys and Ureters.	Inferior Vena Cava.
Liver.	Supra-renal Capsules.	Receptaculum Chyli.
Gall-bladder.	Bladder (when distended.)	Thoracic Duct.
Spleen.	Uterus (during pregnancy.)	Solar Plexus, etc.

Regions of the Abdomen. The abdomen is divided into 9 regions by two horizontal lines,—one between the cartilages of the 9th ribs, another between the crests of the ilia, and 2 vertical lines from the cartilages of the 8th ribs to the centre of Poupart's ligament. The q regions thus formed are named the-

Right Hypochondriac.	Epigastric.	Left Hypochondriac.
Right Lumbar.	Umbilical.	Left Lumbar.
Right Inguinal.	Hypogastric.	Lejt Inguinal.

Parts contained in each region are as follows:—

Right Hypochondriac Region,—contains the right lobe of the liver, hepatic flexure of the colon, and part of the right kidney.

Epigastric Region,—contains the right two-thirds of the stomach, left lobe and part of the right lobe of the liver, gall-bladder, duodenum, cœliac axis, solar plexus, pancreas, parts of the aorta, inferior vena cava, vena azygos, and thoracic duct, the supra-renal capsules and parts of the kidneys.

Left Hypochondriac Region,—contains the fundus of the stomach, spleen, Digitized by Google

19

tail of the pancreas, splenic flexure of the colon, and part of the left kidney.

Right Lumbar Region,-contains the ascending colon, lower half of the right kidney, and part of the small

FIG. 108. EPIGASTRIC LEFT LUMBAR HYPOGASTRIC

intestine.

Umbilical,-contains the transverse colon, transverse duodenum, part of the great omentum and mesentery, and part of the small intestine.

Left Lumbar Region,—contains the descending colon, lower half of the left kidney, and part of the small intestine.

Right Inguinal Region,-contains the right ureter, cæcum, appendix vermiformis, and the spermatic vessels of that side.

Hypogastric Region,—contains convolutions of the small intestine, the bladder in children and in adults when distended, and the uterus during pregnancy.

Left Inguinal Region,—contains the

left ureter and spermatic vessels, and the sigmoid flexure of the colon.

Apertures in the Walls of the Abdomen are 8 in number, for the transmission of structures to or from it, as follows: the-

Opening for the Vena Cava,—in the diaphragm.

Aortic Opening,—behind the diaphragm, for the aorta, vena azygos minor, thoracic duct, and occasionally the left sympathetic nerve.

Esophageal Opening,—in the diaphragm, for the esophagus, and the pneumogastric nerves.

Umbilical Opening,—in the anterior wall, transmitting the umbilical vessels in the fœtus, but obliterated after birth, leaving a puckered depression, named the umbilicus.

Internal Abdominal Ring,—on each side, half an inch above Poupart's ligament, for the passage of the spermatic cord in the male, and the round ligament of the uterus in the female.

Femoral or Crural Ring,—on each side, just below Poupart's ligament; for the passage of the femoral vessels. This opening is closed by the crural septum.

# THE PERITONEUM.

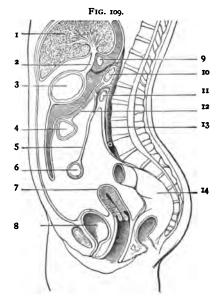

The Peritoneum is a large serous membrane, which forms in the male a closed sac, the parietal layer of which lines the abdominal walls, its visceral layer being reflected more or less completely over all the abdominal and pelvic viscera. Its free surface is covered with squamous epithelium, and is smooth, moist, and shining. Its attached surface is connected to the viscera and the parietes of the abcomen by the sub-peritoneal areolar tissue. In the female it is not a closed sac, the free extremities of the Fallopian tubes opening directly into its cavity. The peritoneum is divided by a constricted portion of its tissue, at the foramen of Winslow (9), into 2 sacs, the—

Greater Sac,—extends over the anterior two-thirds of the liver (1), behind and above the stomach (3); below, behind, and in front of the great omentum, and below the meso-colon (12).

Lesser Sac, or Cavity of the Great Omentum,—extends behind and below

the liver and stomach, above the meso-colon, within the great omentum, and behind the small omentum (2).

The Foramen of Winslow (9) is an opening which connects the two peritoneal sacs with each other. It is formed by an hour-glass constriction of the peritoneum caused by the hepatic artery in its curved passage forward and upward from the coeliac axis to the transverse fissure of the liver. It is situated behind the free border of the lesser omentum (2), immediately below the caudate lobe of the liver, and is bounded as follows:-

Anteriorly, -the lesser omen-

tum (2), containing the hepatic artery, portal vein, and the ductus communis cholédochus.

Posteriorly,—the inferior vena cava, and the right crus of the diaphragm.

Superiorly,—the caudate lobe of the liver.

Inferiorly,—the duodenum, and the hepatic artery.

Nothing passes through the foramen of Winslow.

The Omenta are peritoneal folds which pass from the external surface of the stomach (3) to other organs, and are named the *lesser* or gastrohepatic, the *great* or gastro-colic, and the *gastro-splenic* omentum. The—

Lesser or Gastro-hepatic Omentum (2),—consists of two layers of peritoneum, the anterior layer belonging to the greater sac, the posterior to the lesser sac. It ascends from the lesser curvature of the stomach (3) to the transverse fissure of the liver (1) and the end of the cosophagus. Its right margin is free and rounded, and contains between its layers the—

Hepatic Artery and Portal Vein. Ductus Communis Cholédochus. Hepatic Plexus of Nerves. Lymphatics.

Great or Gastro-colic Omentum,—consists of 4 layers of peritoneum, the most anterior and superior of which belong to the greater sac, the two internal to the lesser sac. The two anterior layers descend from the stomach and spleen over the small intestines (6), and then ascend as the posterior layers to enclose the transverse colon (4).

Gastro-splenic Omentum,—connects the stomach with the spleen, and is continuous by its lower border with the great omentum. It contains the vasa brevia vessels.

The Mesenteries are folds of peritoneum connecting the various parts of the intestinal canal (except the duodenum) to the posterior abdominal wall. Each one contains the vessels of the part which it supports. They are the—

Mesentery proper (5),—connects the convolutions of the jejunum (6) and ileum to the posterior abdominal wall, and contains between its layers the mesenteric vessels and nerves, the lacteals, and the mesenteric glands.

Transverse Meso-colon (12)—connects the transverse colon to the posterior abdominal wall, and is formed by the two posterior layers of the great omentum.

Sigmoid Meso-colon,—connects the sigmoid flexure of the colon to the left iliac fossa.

Meso-rectum,—connects the upper part of the rectum (14) to the front of the sacrum, and contains the superior hemorrhoidal vessels.

Ligaments formed by the Peritoneum are 17 folds of peritoneum which support certain organs, viz.—

Gastro-splenic,—from the stomach to the diaphragm.

Hepatic,—the longitudinal, coronary, and 2 lateral ligaments of the liver.

Splenic,—the suspensory ligament of the spleen.

Vesical,—the false ligaments of the bladder, 5 in number.

Uterine, -2 vesico-uterine, 2 recto-uterine, and 2 lateral or broad ligaments of the uterus.

Pouches formed by the Peritoneum, as it passes over the rectum (14), vagina, uterus (7) and bladder (8), are as follows: the—

Recto-vesical Pouch,—in the male, between the rectum and the bladder. Recto-vaginal or Douglas' Pouch,—in the female, between the rectum and the posterior vaginal wall.

Utero-vesical Pouch,—in the female, between the anterior wall of the uterus and the posterior wall of the bladder.

Retro-peritoneal Fossæ are recesses of the peritoneum, forming small pouches in certain parts of the abdominal cavity; any one of which may be the site of a retro-peritoneal hernia, and hernia of the vermiform appendix frequently occurs into one of the pericæcal group. The lesser sac of the peritoneum may be regarded as a recess of peritoneum through the foramen of Winslow. The others are divided into 3 groups, as follows:—

Duodenal Fossæ,—9 have been described, of which 3 are fairly constant, viz.; the inferior, and superior, both on the left side of the ascending portion of the duodenum (11); and the duodeno-jejunal, bounded above by the pancreas (10), below by the left renal vein, to the right by the aorta (13), and to the left by the left kidney.

Pericæcal Fossæ,—are the ileo-colic, in front of the cæcum; the ileo-cæcal, behind the angle of junction of the ileum and cæcum; and the sub-cæcal, immediately behind the cæcum.

Intersigmoid Fossa,—lies behind the sigmoid meso-colon, and in front of the parietal peritoneum, on the external iliac vessels. It is constant in the fœtus and during infancy, but disappears in a certain percentage of cases as age advances.

Appendices Epiploicæ,—are small pouches of peritoneum situated along the colon and upper third of the rectum, and filled with fat. They are chiefly found along the transverse colon.

# Viscera invested by Peritoneum are the following-named:—

Liver (1) (almost wholly). Stomach (3) (almost wholly).

Spleen.

Duodenum (11) (first part).

Small Intestine (6).

Transverse Colon (4).

Sigmoid Flexure. Rectum (upper  $\frac{1}{3}$ ).

Ovaries.

Uterus (7).

Those partially invested by peritoneum are the—

Duodenum (descending and

transverse portions).

Cæcum.

Ascending Colon.

Descending Colon.

Rectum (14) (middle third).

Vagina (upper part).

Bladder (8) (posterior wall).

Those having no peritoneal investment are the-

Pancreas (10).

Kidneys.

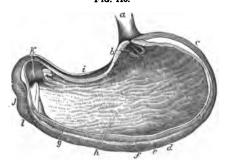

Supra-renal Capsules.

Demonstration of the Peritoneum is best made with a large bag of mosquito-netting, closed along all four sides, but having a central slit to represent the incision usually made in the laparotomy operation. Sponges of various sizes will represent the various organs, and may be pushed into folds of the bag and tied in by string, wholly or partially covered, as the case may be, for each. Professor Pancoast used this method of demonstration in his lectures, making the subject perfectly clear to many who never understood it before.

# THE STOMACH.

The Stomach, the principal organ of digestion, is a dilated part of the alimentary canal, situated between the termination of the œsophagus and the beginning of the small intestine. It is somewhat pyriform in shape, of musculo-membranous structure, about 12 inches long by 4 inches in average diameter, held in position by the lesser omentum, and situated diagonally across the upper abdomen, in the epigastric and left hypochon-

FIG. 110.

driac regions, above the transverse colon, below the liver and diaphragm. It presents for examination a—

Fundus or Splenic End (c),
—connected to the
spleen by the gastrosplenic omentum, (see
under Peritoneum).

Pylorus or Lesser End, lies in contact with the anterior wall of the abdomen, the under surface of the liver,

and the neck of the gall-bladder, its position being near the end of the cartilage of the 8th rib.

Greater Curvature (d),—is convex, and is connected to the colon by the great omentum.

Lesser Curvature (i),—is concave, and connected to the liver by the lesser omentum, and to the diaphragm by the gastro-phrenic ligament.

Esophageal Orifice (b),—is situated between the fundus and the lesser curvature. It is funnel-shaped, and the highest part of the organ.

Pyloric Orifice (k),—opens into the duodenum (l), and is guarded by the circular muscular fibres of the pylorus, which are aggregated into a circular ring, projecting into the cavity, and with its covering fold of mucous membrane, forming the pyloric valve.

Structure of the Stomach. Its wall consists of 4 coats,—the serous, muscular, areolar, and mucous; together with vessels and nerves. The—

Serous Coat,—is derived from the peritoneum, and covers the whole external surface, excepting the points where the gastro-splenic, great and lesser omenta are attached, and where the stomach is in contact with the diaphragm.

Muscular Coat (f),—consists of longitudinal, circular, and oblique fibres. The longitudinal fibres radiate from the cardiac orifice, are continuous with the longitudinal fibres of the œsophagus and the small intestine, and are the most superficial. The circular fibres lie deeper, form a layer over the whole organ, and are aggregated into a circular ring at the pyloric end, which, with its lining mucous fold forms the pyloric valve. The oblique fibres lie deepest, and are arranged in two sets around the cardiac end.

Areolar or Sub-mucous Coat,—consists of loose areolar tissue, connecting the muscular and mucous coats, and contains the gastric vessels.

Mucous Coat (g),—lined with columnar non-ciliated epithelium, covered with polygonal alveoli,  $_{110}^{11}$  of an inch in diameter, containing the orifices of the gastric glands. When the stomach is contracted the mucous membrane lies in longitudinal folds or rugx (h), one of which aids in forming the valve at the pyloric orifice.

Gastric Glands are of two kinds, named pyloric and cardiac glands, both tubular in character, and formed by a delicate basement membrane, lined by epithelium. The—

Pyloric Glands,—are most numerous at the pyloric end; each consists of 2 or 3 short, closed tubes, opening into a common duct, the orifice of which is situated at the bottom of an alveolus. They are lined with columnar epithelium throughout.

Cardiac Glands,—situated all over the stomach, but most numerous toward the cardiac end, are tubules lined part way with columnar epithelium, and filled with nucleated cells in their deepest parts.

Vessels and Nerves. The Arteries of the stomach are—the gastric, the

pyloric and right gastro-epiploic branches of the hepatic, the left gastro-epiploic and vasa brevia from the splenic. The—

Veins,—terminate either in the splenic and superior mesenteric veins, or directly in the portal vein.

Nerves,—are terminal branches of the right and left pneumogastrics, and 'branches of the semilunar ganglia of the sympathetic, forming the gastric plexus, (see page 212).

#### THE SMALL INTESTINE.

The Small Intestine is a convoluted, tubular, digestive organ, about 20 feet in length, extending from the pylorus to the ileo-cæcal valve, where it terminates in the large intestine. It is connected to the spinal column by

the mesenteric portion of the peritoneum, and divided into 3 parts, the— Duodenum (d),—about 10 inches

long, ascends for 21 inches to the under surface of the liver and the neck of the gall-bladder, descends for 31 inches in front of the right kidney, and passes transversely for 4 inches to the left, across the spinal column, to the left side of the second lumbar vertebra, where the superior mesenteric artery crosses its junction with the jeju-The duodenum has no num. mesentery, is partially covered with peritoneum, and surrounds the head of the pancreas. Into its descending portion open the ductus communis cholédochus and the pancreatic duct.

Jejúnum,—about two-fifths of the rest of the small intestine, its coils lying around the umbilical region. It is named from the fact that it was formerly supposed to be found empty (jejunus) after death.

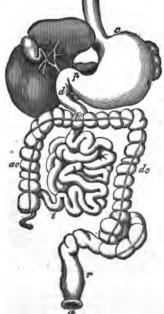

FIG. 111.

death.

Ileum (i),—comprises the remainder of the small intestine; is named from

its twisted course, lying below the umbilicus, and terminating in the right iliac fossa, at the *ileo-cœcal valve*, or valve of Bauhin.

Meckel's Diverticulum,—is a blind tube occasionally found connected with the ileum, about 3½ feet above its termination; and represents the remains of the vitelline duct of early feetal life.

Structure of the Small Intestine, is arranged in 4 coats, like that of the stomach, a serous, muscular, areolar, and mucous coat. The—

Serous Coat,—is derived from the peritoneum, which partially invests the duodenum, and completely invests the jejunum and ileum, except for a small space along their mesenteric border, where the vessels and nerves pass in.

Muscular Coat,—consists of external longitudinal and internal circular fibres, the former being thinly distributed along the bowel, the latter forming a thick layer, but not making complete rings.

Areolar Coat,—contains the vessels of the intestine, and connects the other two coats together.

Mucous Membrane,—is covered with columnar non-ciliated epithelium, and thrown into crescentic transverse folds, the valvulæ conniventes, or valves of Kirkring. It presents also numerous vascular projections or Villi, simple follicles, and three kinds of glands, (all described below).

**Villi** (f) are minute, vascular processes, which project from the mucous membrane of the small intestine throughout its whole extent, giving to its surface a velvety appearance. They are most numerous in the duodenum

and jejunum, and altogether number about 4 millions for the whole length of the intestine. Each villus consists of a lacteal vessel, a plexus of capillary blood-vessels, epithelium, basement membrane, and muscular tissue, supported and held together by retiform lymphoid tissue. The—

Lateal Vessel,—is situated in the axis of the villus, and commences by dilated extremities near its summit.

Blood-vessels,—form applexus between the lacteal and the basement membrane, enclosing the cells of the villus in their interstices.

Basement Membrane, - surrounds the preced-

ing, and is made up of a stratum of endothelial cells, upon which is a layer of columnar epithelium.

Muscular Tissue,—consists of longitudinal fibres prolonged into the villus from the muscular tissue of the mucosa.

Simple Follicles, or Crypts of Lieberkühn,—are minute, tubular depressions of the mucous membrane, opening between the villi, their orifices appearing as minute dots on the surface of the mucous membrane.

Glands of the Small Intestine. The mucous membrane of the small intestine contains the following glands:—

Duodenal or Brunner's Gland,—are small, compound glands, found only in the duodenum and the first part of the jejunum, being most numerous near the pylorus. In structure they are identical with the racemose glands of the mouth.

Solitary Glands,—are lymphoid organs, situated throughout the intestine, though most numerous at the lower portion of the ileum. They are agminated into some 20 or 30 oval patches, named—

Peyer's Glands,—on the surface opposite to the mesenteric attachments, some of which are as much as 4 inches in length. They are most numerous and largest in the ileum, are few and small in the jejunum, and are occasionally seen in the duodenum.

Vessels and Nerves. The Arteries of the jejunum and ileum are branches of the superior mesenteric artery, forming an intricate plexus in the areolar tissue, which gives off minute vessels to the glands and villi. The duodenum is supplied by the pyloric and pancreatico-duodenal branches of the hepatic, and the inferior pancreatico-duodenal from the superior mesenteric. The—

Veins,—accompany the arteries and have a similar course and arrangement.

Lymphatics,—are in two sets, one for the mucous membrane and one for the muscular coat.

Nerves,—of the duodenum are derived from the solar plexus; those of the rest of the intestine from the sympathetic plexuses around the superior mesenteric artery.

# THE LARGE INTESTINE.

The Large Intestine extends from the termination of the ileum to the anus. It is about five feet long, of large calibre, and consists of the same coats as the small intestine, the mucous being smooth and without villi, the muscular having its longitudinal fibres collected into 3 narrow bands, producing a sacculation (pouching) of its wall. In its course it describes an arch around the convolutions of the small intestine, and is divided into 3 portions, the Cæcum, the Colon, and the Rectum.

The Cæcum is a large blind pouch, about 2½ inches long and 3 inches

broad, situated in the right iliac fossa, immediately behind the abdominal wall, above the outer half of Poupart's ligament, and below the ileo-cæcal valve, which opens into it. It lies free in the abdominal cavity, its closed end downward, its open end upward and continuous with the commencement of the colon. It is usually enveloped entirely by peritoneum, and presents for examination the—

Vermijorm Appendix,—a narrow, worm-like, blind tube, averaging 3 inches in length, directed upward behind the cæcum, or to the left behind the ileum, or downward and inward into the true pelvis. Its canal communicates with the cæcum by an orifice situated below and behind the ileo-cæcal opening. Its proximal 3rds is retained in position by a triangular mesentery, its distal 3rd is free and completely covered by peritoneum.

Ileo-cæcal Valve, or Valve of Bauhin,—guards the entrance of the small intestine, and is formed by two crescentic folds of the mucous and cellular coats and circular muscular fibres, each fold being covered with villi on the side toward the ileum, but smooth on the cæcal side.

The Colon is divided into 4 parts,—the ascending, transverse, and descending colon and the sigmoid flexure. The Ascending Colon (ac) extends from the cæcum upward on the right side of the abdominal cavity, to the under surface of the liver, where it turns to the left, forming the hepatic flexure. The Transverse Colon (tc) crosses the abdomen from right to left to the lower end of the spleen, where it curves downward, forming the splenic flexure. The Descending Colon (dc) passes downward along the outer border of the left kidney, then inward along the outer border of the psoas muscle to the crest of the ilium, where it terminates in the Sigmoid Flexure. The latter is curved like an f, first upward and forward, then downward into a loop, which terminates in the rectum, opposite the left sacro-iliac symphysis. The—

Peritoneum,—covers the transverse colon and the loop of the sigmoid flexure almost completely, forming the transverse mesocolon and the sigmoid mesocolon. It covers the ascending and descending colon and the upper part of the sigmoid flexure on their anterior surface and sides.

Mesocolon,—is the mesentery of the colon, connecting the transverse portion to the posterior abdominal wall in all cases; but exists for the ascending colon in 26 per cent., and for the descending colon in 36 per cent. of the cases. The sigmoid mesocolon connects the loop of the sigmoid flexure to the psoas muscle.

Phreno-colic Ligament,—is a fold of peritoneum, connecting the commencement of the descending colon with the diaphragm

Appendices Epiploicæ,—are small pouches of peritoneum containing fat, and found along the colon and part of the rectum. They are chiefly appended to the transverse colon.

The Rectum (r) is the terminal portion of the large intestine, and extends from the sigmoid flexure to the anal orifice (a). It is about 8 inches long, not sacculated, and, though not straight, is straighter than the rest of the gut. It curves laterally to the middle of the sacrum, and backward about an inch above its termination at the anus, where it forms an antero-posterior slit, having its lateral walls in apposition, but capable of considerable distention. The relations of the rectum are as follows:—

First Portion, 4 inches long,—lies on the left pyriformis muscle and the left sacral plexus of nerves; to its left are the left ureter and the branches of the left internal iliac artery.

Second Portion, 3 inches long,—in the male subject lies just behind the trigonum vesicæ and the vesiculæ seminales, and close below the under surface of the prostate gland. In the female it is adherent to the central portion of the posterior wall of the vagina.

Third Portion or Anal Canal, 1 to 1½ inch long,—is surrounded by its sphincters and the levator ani muscle, and is separated by the perinæum from the membranous portion and bulb of the urethra in the male, from the vagina in the female.

Peritoneum,—invests the first portion almost completely, forming the mesorectum, which connects it to the sacrum; invests the second portion in front and laterally, and is thence reflected to the bladder in the male and to the vagina in the female. The third portion of the rectum has no peritoneal investment.

Sphincters of the Rectum,—are the internal sphincter and the sphincter ani, (see page 95).

Valves of Houston,—are 3 transverse folds of the mucous lining, of semilunar shape, one in the upper part of the rectum on the right side, another about the middle on the left side, and the third in front, opposite the base of the bladder.

Glands of the Large Intestine. The simple follicles are present throughout its entire length, and are more numerous than in the small intestine. The solitary glands are most abundant in the cæcum and appendix, but are scattered irregularly over the entire canal. Brunner's glands and villi are absent, the valvulæ conniventes are almost wanting.

Vessels and Nerves. The Arteries of the large intestine are the ileocolic, colica dextra and colica media from the superior mesenteric, to the

cæcum, the ascending colon and the transverse colon; the colica sinistra and sigmoid branches of the inferior mesenteric, to the descending colon and the sigmoid flexure; the superior hemorrhoidal from the inferior mesenteric, the middle hemorrhoidal from the internal iliac, and the inferior hemorrhoidal from the pudic, to the rectum. The—

Veins of the Rectum,—commence in a plexus around the lower end, the hemorrhoidal plexus, which gives off 6 vessels to unite into a trunk, the superior hemorrhoidal vein. The plexus communicates also with the tributaries of the middle and inferior hemorrhoidal veins, establishing a communication between the systemic and portal circulations.

Lymphatics,—open into the mesenteric, lumbar, sacral and inguinal glands, the latter receiving the vessels from around the anus.

Nerves,—are derived from the sympathetic plexuses around the arteries which are distributed to the large intestine.

## THE LIVER.

The Liver is the largest gland in the body, weighing from 3 to 4 pounds, and measuring all the way from 3 to 9 inches in various directions. It is situated in the right hypochondriac, epigastric and part of the left hypochondriac regions; has 5 fissures, 5 lobes, 5 ligaments, and 5 sets of vessels, and is invested by peritoneum, except for a small space at the attachment of the coronary ligament. It is also surrounded by a fibrous coat which is continuous at the transverse fissure with the capsule of Glisson. Its—

Upper Surface,—is convex, in relation with the under surface of the diaphragm and 6 or 7 lower ribs, and is divided into two lobes by the suspensory or broad ligament.

Under Surface (Fig. 113),—is concave, covers the stomach, duodenum, hepatic flexure of colon, right kidney and supra-renal capsule, and is divided into 5 lobes by 5 fissures.

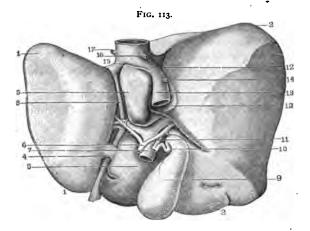

Anterior Border,—is sharp, and is notched in two places, one at the fundus of the gall-bladder, the other at the round and falciform ligaments. It corresponds to the lower border of the ribs and costal cartilages, descending a little lower during deep inspiration and in the upright posture.

Posterior Border,—rounded, and deeply grooved (sometimes channeled) for the inferior vena cava (13).

Fissures of the Liver are 5 in number, situated on the inferior and posterior surfaces, and arranged in the form of the letter H. The left limb of the H is the longitudinal fissure, divided into the umbilical fissure anteriorly, and the fissure for the ductus venosus (8) posteriorly; the right limb

is formed in front by the fissure for the gall-bladder (9), behind by the fissure (12) for the vena cava (13). The connecting bar of the H is the transverse fissure. The—

Longitudinal Fissure,—separates the left lobe from the lobus Spigelii

and the lobus quadratus. Its anterior portion, in front of the transverse fissure, is the *umbilical fissure*, containing the umbilical vein in the fœtus, and its remains, the round ligament, in the adult. Its posterior portion is the *fissure of the ductus venosus* (8), and lodges the slender cord which, in the adult, represents that fœtal vessel.

Transverse or Portal Fissure,—is about 2 inches long, runs from the longitudinal fissure to the right, and transmits the portal vein (7), hepatic artery (6) and nerves, and the hepatic duct (11) and lymphatics. It separates the quadrate lobe in front from the caudate and Spigelian lobes behind.

Fissure for the Gall-bladder (9),—on the right of the longitudinal fissure, and nearly parallel with it, extending from the anterior border, backward to near the right end of the transverse fissure.

Fissure for the Vena Cava (12),—extends obliquely upward on the posterior surface, and separates the Spigelian lobe from the right lobe. Occasionally this fissure is a complete canal in the substance of the liver.

Lobes of the Liver are 5 in number, but three are mere lobules of the right lobe, formed by the smaller fissures. The—

- Right Lobe (2),—is much the largest, and presents the three small fissures and four shallow depressions, one anteriorly for the colon, another posteriorly for the kidney, a third for the duodenum, and a fourth for the supra-renal capsule.
- Left Lobe (1),—is divided from the right lobe by the longitudinal fissure, and rests upon the stomach.
- Lobus Quadratus (3),—in front of the transverse fissure, and between the umbilical fissure and that for the gall-bladder.
- Lobus Spigelii (5),—behind the transverse fissure, and between the fissure for the ductus venosus and that for the vena cava.
- Lobus Caudatus (4),—a connecting ridge from the lobus Spigelii to the right lobe; it separates the fissure for the vena cava from the fissure for the gall-bladder, and lies directly above the foramen of Winslow.

Ligaments of the Liver are 5 in number, connecting the organ to the under surface of the diaphragm and the anterior wall of the abdomen. Four are folds of peritoneum; one, the round ligament, is the obliterated umbilical vein of the fœtus. The—

- Suspensory or Falciform Ligament, called also the Broad and the Longitudinal Ligament,—is a sickle-shaped double fold reflected over the round ligament, and is attached to the sheath of the right rectus muscle as low as the umbilicus, and to the diaphragm.
- Coronary Ligament,—is a double fold, containing firm areolar tissue in its interspace, and extending from the posterior border of the liver to the diaphragm.
- Lateral Ligaments 2,—are the triangular extremities of the coronary ligament, and extend from the liver to the diaphragm.
- Round Ligament,—ascends in the free margin of the suspensory ligament from the umbilicus to the longitudinal fissure, in which it is continued to the vena cava. It results from the obliteration of the fœtal umbilical vein, and is continued on the posterior surface as the obliterated ductus venosus (8).

# STRUCTURE OF THE LIVER.

The Liver Substance is composed of numerous lobules held together by fine areolar tissue, and the ramifications of the hepatic artery and veins, portal vein, hepatic ducts, lymphatics and nerves. The whole organ is invested by a fibrous coat, and by a peritoneal coat for the greater part of its surface. The—

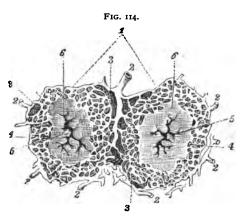

Fibrous Coat,—is formed of connective tissue, and is inflected at the transverse fissure along the vessels, forming the so-called capsule of Glisson.

Peritoneal Coat,—is derived from the gastro-hepatic (lesser) omentum,

between the layers of which the liver is received, and which forms 4 of its 5 ligaments.

Parts Uncovered by Peritoneum are—on the anterior and superior surfaces, along the line between the two layers which form the suspensory ligament; on the inferior surface, where the gall-bladder is attached, and at the transverse fissure where the vessels enter; on the posterior surface of the right lobe, a strip about 3 inches broad, where the liver is in contact with the diaphragm, also a part of the depression for the supra-renal capsule.

The Lobules (1) are small, granular-looking bodies, of polygonal

shape, and about  $\frac{1}{20}$  inch in diameter, clustered around the sub-lobular branches of the hepatic veins, and connected together by connective tissue (3), blood-vessels, ducts (2), and lymphatics. Each lobule consists of a mass of hepatic cells, surrounded by a dense capillary plexus, and contains the minute beginnings of a bileduct, the so-called biliary capillaries; possessing therefore all the

essential constituents of a secreting gland. A lobule contains-

Hepatic Cells,—each about T500 inch in diameter, having a nucleus and nucleolus, yellow coloring matter, glycogen granules, and oil globules.

Lobular Veins (3),—forming a plexus in the lobule.

Intralobular Vein (4),—in the centre of each lobule.

Plexuses,—of lymphatics, nerves, and bile-ducts.

The Capsule of Glisson is the fibrous tissue which surrounds the hepatic vessels in the transverse fissure, and accompanies them in their course throughout the substance of the liver. It is continuous with the fibrous covering of the organ.

Nerves of the Liver are branches from the hepatic plexus, which is formed by branches derived from the coeliac plexus, the left pneumogastric and the right phrenic nerves.

# VESSELS OF THE LIVER.

Vessels of the Liver are 5 in number, the hepatic artery, portal vein, hepatic veins, hepatic ducts, and lymphatics, all emerging in the transverse fissure except the hepatic veins, which enter the fissure for the vena cava. In the transverse fissure the vessels are enveloped in the capsule of Glisson, and the duct, artery and vein are situated from before backward in the order named, represented by the letters DAV. Four of these vessels are described separately below, the—

Lymphatics,—accompany the blood-vessels in 2 sets, superficial and deep; the latter beginning in lymphatic spaces around the capillaries of the lobules, and accompanying the interlobular vessels. They enter the lumbar glands, the glands of the lesser omentum, those of the œsophagus and of the lesser curvature of the stomach.

The Hepatic Artery is the nutrient vessel of the liver; it arises from the cœliac axis, gives off pyloric, gastro-duodenal and cystic branches, and passes upward in front of the foramen of Winslow to the transverse fissure, where it divides into right and left branches, for the corresponding lobes

of the liver. These divide and subdivide, ramifying in the portal canals throughout the organ, and giving off the following branches:—

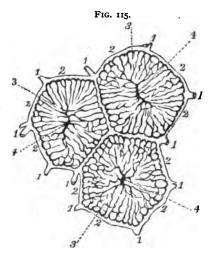

Vaginal Branches,—to the capsule of Glisson.

Capsular Branches,—to the fibrous covering of the liver.

Interlobular, — forming an arterial plexus between the lobules.

Lobular,—to the capillary network in the lobules.

The Portal Vein brings blood to the liver from the stomach, intestines, pancreas and spleen; being formed by the union of the superior and

inferior mesenteric, splenic and gastric veins, all the main veins of the abdomen except the renal. It is about 4 inches long, enters the transverse fissure of the liver, where it divides into the *right* and *left portal* veins,

these dividing into branches, which receive vaginal and capsular veins, and ramify throughout the liver as portal canals (1), in company with the branches of the hepatic artery and duct; finally breaking up into the—

Interlobular Plexus (2),—between the lobules, giving off the—

Lobular Veins (3),—converge to the centre of the lobule, and end in the— Intralobular Vein (4),—vertically in the centre of each lobule, enters the sublobular of the hepatic veins below the lobule.

The Hepatic Veins convey blood away from the liver, and are continuations of the intralobular veins of the portal system, beginning as the sublobular veins below each lobule, uniting finally into 3 trunks usually, which enter the inferior vena cava in the fissure for that vessel. On section of the liver the hepatic veins gape open, being adherent to the liver substance; the portal veins are closed, being surrounded by the capsule of Glisson.

The Hepatic Ducts carry away bile from the liver. They begin between the cells of the lobules, in minute spaces, the bile-capillaries, forming channels which radiate to the circumference of the lobule, and enter an interlobular plexus between the lobules; from which plexus ducts pass into the portal canals; are enclosed in the capsule of Glisson with the portal vein and the hepatic artery, and join with other ducts to finally form 2 main trunks, which emerge at the transverse fissure, and by their union form the Hepatic Duct, (see below).

# EXCRETORY APPARATUS OF THE LIVER.

The Excretory Apparatus of the liver consists of—the Hepatic Duct, formed by the union of the two main trunks above-mentioned; the Gall-bladder, a reservoir for the bile; the Cystic Duct, the duct of the gall-bladder; and the Ductus Communis Cholédochus or common bile-duct, formed by the junction of the hepatic and cystic ducts. The—

Hepatic Duct,—about 1½ inch long; is formed in the transverse fissure by the union of the two main biliary ducts, from the right and left lobes. It joins the cystic duct from the gall-bladder to form the—

Ductus Communis Cholédochus, or Common Bile-duct,—is a fibro-muscular tube, covered by peritoneum and lined with mucous membrane, about 3 inches in length, formed by the junction of the Cystic and Hepatic ducts, and emptying its contents (bile) into the descending part of the duodenum at a point about 3 inches from the pyloric orifice of the stomach, generally in common with the duct of the pancreas.

The Gall-bladder is a pear-shaped bag, 3 to 4 inches long, an inch in greatest diameter, holding from 8 to 12 fluid drachms, invested by perito-

neum on its under surface and fundus, formed of a fibro-muscular coat and lined by a mucous one, lying in a fissure on the under surface of the liver, close to its anterior border, and directed obliquely downward, forward, and to the right. Its—

Fundus,—touches the abdominal wall immediately below the 9th costal cartilage, and is completely invested by peritoneum.

Neck,—is narrow and curves like the letter S; it empties into the—

Cystic Duct,—about 1½ inch long, is marked interiorly by spirally arranged crescentic folds of its mucous lining, and joins with the hepatic duct at an acute angle, to form the common bile-duct, (see above).

# THE PANCREAS.

The Pancreas is a compound racemose gland, about 5½ inches long and 1½ inch broad, situated transversely across the posterior wall of the abdomen behind the stomach and in front of the first lumbar vertebra. Its structure resembles that of the salivary glands, being composed of reddishyellow lobules, vessels and ducts, and ending in closed pouches surrounded by a capillary plexus. It is not enclosed in a capsule, but is surrounded by areolar tissue, which extends into its interior, and connects together the various lobules. Its—

Head or Right Extremity (1),-shaped like the head of a hammer, lies

in the concave curve of the duodenum, in front of the common bile-duct, the inferior vena cava, the left renal vein, the right crus of the diaphragm, and the aorta.

Neck (2),-about an inch

long, lies just below the pylorus, and above the transverse portion of the duodenum.

Body (3),—is in relation anteriorly with the ascending layer of the transverse meso-colon, the posterior wall of the stomach and the transverse colon; posteriorly with the aorta, splenic vein, origin of the superior mesenteric artery, crura of the diaphragm, left kidney and supra-renal capsule, and the left quadratus lumborum muscle.

Tail, or Left Extremity (4),—lies above the left kidney and in contact with the lower part of the inner surface of the spleen.

Pancreatic Duct, or Duct of Wirsung (5),—extends the whole length of the gland, commencing by the junction of the lobular ducts in the

tail, it receives the ducts of the various lobules, and opens into the descending portion of the duodenum, about 3 or 4 inches below the pylorus, usually by an orifice common to it and the common bile-duct, occasionally by a separate orifice.

Arteries, are the-

Pancreatica Magna and Pancreaticæ Parvæ,—from the splenic.

Pancreatico-duodenalis,—branch of the hepatic artery.

Inferior Pancreatico-duodenalis,-branch of the sup. mesenteric.

· Veins,—open into the splenic and superior mesenteric veins.

Lymphatics,—terminate in the lumbar glands.

Nerves,—are filaments from the splenic plexus, which is a subdivision of the coeliac plexus.

The Lesser Pancreas is a lobe of the head of the pancreas, sometimes found detached, in which case it opens by a duct into the duodenum about an inch above the orifice of the pancreatic duct.

# THE SPLEEN.

The Spleen is one of the ductless glands, and is a soft, brittle, highly vascular organ, of dark purplish color, in size about 5 by 3 by 1½ inches, in weight about 7 ounces; situated deeply in the left hypochondrium, between the fundus of the stomach in front and internally, and the diaphragm behind and externally, opposite the 9th, 10th and 11th ribs of the left side. It is connected with the stomach, by the gastro-splenic omentum (see page 292); with the diaphragm, by the suspensory or phreno-splenic ligament; and with the left kidney, by the lieno-renal ligament, all of which are folds of peritoneum. Its—

Outer Surface,—is convex, smooth, and in relation with the under surface
of the diaphragm, which separates it from the 9th,
Fig. 117. 10th and 11th ribs of the left side.

Inner Surface,—is concave, and in contact, anteriorly (2) with the posterior wall of the cardiac end of the stomach and the tail of the pancreas,

posteriorly (1) with the left kidney.

Hilum,—a vertical fissure about the middle of the inner surface, pierced by apertures for the vessels and nerves.

Lower End,—is flat and triangular, and rests upon the splenic flexure of the colon and the phrenocolic ligament.

Structure of the Spleen. A fibro-elastic capsule, the tunica propria,

forms the framework of the spleen. It invests the organ externally, is reflected inward at the hilum along the vessels, and gives off from both parts bands or trabeculæ, which traverse the organ in all directions and unite with each other, to form a sponge-like structure, having numerous primary spaces or areola, in which the pulp is contained. The splenic pulp looks like a soft, dark-red mass, resembling grumous blood, but consists of branching connective-tissue corpuscles, the supporting or sustentacular cells, which form a delicate reticulated tissue, making within the areolæ a number of secondary spaces, in which is blood containing a large proportion of white blood-corpuscles, also red blood-corpuscles in all stages of disintegration. These secondary spaces are continuous with the terminal arterial capillaries and the primary venous radicles, both of which open into them, bringing the blood supply into relation with the pulp elements. The connective-tissue coat of the arteries is converted into a lymphoid tissue in the arterioles, and this tissue presents thickenings of spheroidal shape, the—

- Malpighian Bodies,—vary from 100 to 10 inch in diameter, and are attached to the arterioles of the organ in groups of 6 or 8. Their reticulum is slender and open, densely filled with lymphoid cells, and well supplied with capillaries.
- Peritoneal, or Serous Coat,—covers the whole organ, except at the hilum and the attachments of the suspensory ligament and the gastro-splenic omentum.
- Splenic Artery,—is large and tortuous, and divides at the hilum into 5 or 6 branches (4), each supplying a segment of the organ, and terminating in capillaries which open into the secondary spaces.
- Veins,—arise by radicles from the secondary spaces, and anastomose freely, joining to form 6 or more branches (5) which emerge from the hilum and unite into the splenic vein, the largest of the constituents forming the portal vein.
- Lymphatics,—are superficial and deep; the two sets joining in the interior of the organ, pass through the lymphatic glands at the hilum, and terminate in the thoracic duct.
- Nerves,—are branches of the splenic plexus, which is formed by branches from the cœliac plexus, the left semilunar ganglion, and the right pneumogastric nerve.

Other Ductless Glands are the Thyroid and Thymus Glands, and the Supra-renal Capsules. The first two are described with the organs of voice and respiration, the supra-renal capsules are described with the kidneys.

# ORGANS OF VOICE AND RESPIRATION.

## THE LARYNX.

The Larynx is a musculo-membranous-cartilaginous box, the essential organ of voice, placed at the upper end of the air-passage, between the trachea and the base of the tongue, in the upper and fore part of the neck, where it forms a projection in the middle line. Its cartilages are o in number, 3 single and 3 in pairs, the-

> Thyroid Cartilage. Cricoid Cartilage. Epiglottis.

Arytenoid Cartilages 2. Cuneiform Cartilages 2. Cornicula Laryngis 2.

The Thyroid Cartilage, or shield-like cartilage, consists of two Ala or wings (b), united in front at an acute angle, the highest portion of its front being called the Pomum Adami, Adam's apple. Its-

Outer Surface,—affords attachment to the sterno-thyroid, thyro-hyoid and inferior constrictor muscles; the two first being attached along its oblique ridge.

Upper Border,—is curved irregularly, has the thyroid notch (d) in front, and gives attachment to the thyro-hyoid membrane.

FIG. 118.

Lower Border,—gives attachment to the crico-thyroid membrane in the median line and on each side to the crico-thyroid muscle.

Inner Surface,—gives attachment to the true and false vocal cords, the epiglottis, thyro-arytenoid and thyro-epiglottidean muscles, and the thyroepiglottidean ligament.

Posterior Border—of each wing ends above and below in cornua (horns), and gives attachment to the stylo- and palato-pharyngeus muscles.

Superior Cornu (a)—of each side affords attachment to the thyro-hyoid ligament.

Inferior Cornu (c)—of each side articulates with the cricoid cartilage by a small oval facet.

The Cricoid Cartilage, so called from its ring-like shape, is situated below the thyroid, with its narrow part to the front. It has on each side 2 articular facets, one on the upper margin posteriorly for the arytenoid cartilage, and one near the lower margin for the inferior cornu of the thyroid cartilage. Its-

Posterior Portion,—is deep and broad, gives attachment in the middle

line to the longitudinal fibres of the œsophagus, and on each side to the crico-arytenoidus posticus muscle.

Anterior Portion,—is narrow and convex, and affords attachment to the crico-thyroid muscles and part of the inferior constrictor.

Fig. 119.

Upper Border,—affords attachment to the crico-thyroid membrane and the crico-arytenoidei laterales muscles, and articulates with the arytenoid cartilages.

Lower Border,—is connected to the upper ring of the trachea by fibrous membrane.

The Arytenoid Cartilages, or pitcher-like cartilages, are 2 in number, pyramidal-shaped, and situated on the upper margin of the cricoid cartilage posteriorly, closing in the back of the larynx. Each cartilage has 3 surfaces, 2 angles, a base and an apex. The—

F1G. 120.

Anterior Angle,—gives attachment to the true vocal cord and the thyro-arytenoideus muscle.

Posterior Surjace.—has attached to it the arytenoideus.

Posterior Angle,—gives attachment to the crico-arytenoideus lateralis and posticus muscles.

Internal Surjaces of each—look toward each other.

Base,—has a facet for articulation with the cricoid.

A pex,—articulates with the corniculum laryngis.

The Cornicula Laryngis are 2 small cartilaginous nodules attached to the apices of the arytenoid cartilages, and are also called the Cartilages of Santorini. To them are attached the aryteno-epiglottidean folds.

The Cuneiform Cartilages, or Cartilages of Wrisberg, are 2 rods of yellow elastic cartilage contained in the free borders of the aryteno-epiglottidean folds, one on each side, just in front of the arytenoid cartilages.

The Epiglottis is a cartilaginous lid for the larynx. It is leaf-shaped, situated behind the base of the tongue, and attached by its apex to the posterior surface of the thyroid cartilage, just below the median notch. Its—

Base,—is free, and curves over the base of the tongue.

Apex,—is connected to the receding angle of the thyroid cartilage by the thyro-epiglottic ligament.

Anterior Surface,—is attached to the hyoid bone by the hyo-epiglottic ligament, and to the tongue by 3 glosso-epiglottidean folds.

Posterior Surface,—covers the superior aperture of the larynx when food passes through the pharynx.

Lateral Margins,—are connected to the arytenoid cartilages by the arytenoepiglottidean folds.

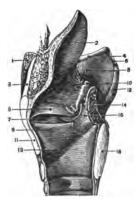

Ligaments of the Larynx are 20 in number,—8 Extrinsic Ligaments, connecting the larynx to the hyoid bone (1), the tongue, and the trachea (15); and 12 Intrinsic Ligaments, binding its several cartilages together. The Extrinsic Ligaments 8 are the—

Hyo-epiglottic Ligament,—connecting the hyoid bone (1) with the epiglottis (2).

Glosso-epiglottic Folds (3),—from the tongue to the epiglottis.

Thyro-hyoid Membrane (3),—connecting the thyroid cartilage (11) with the hyoid bone (1), and bounded laterally by the two—

FIG. 121.

Lateral Thyro-hyoid Ligaments (6)—each containing a nodule of cartilage, the cartilago triticea.

Crico-tracheal Ligament,—from the cricoid cartilage (18) to the trachea.

Intrinsic Ligaments 12, are the-

Thyro-epiglottic Ligament,—connecting the thyroid cartilage (11) with the epiglottis (2).

Crico-thyroid Membrane (13),—connecting the cricoid (18) and thyroid (11) cartilages.

Crico-thyroid Capsular Ligaments 2,—enclosing those articulations.

Crico-arytenoid Ligaments 2,—connect the cricoid and arytenoid cartilages together.

Crico-arytenoid Capsular Ligaments 2,—

enclosing those articulations.

Superior Thyro-arytenoid Ligaments 2,—in the false vocal cords (5). Inferior Thyro-arytenoid Ligaments 2,—in the true vocal cords (9).

Interior of the Larynx presents a cavity which is divided into two parts by the projection inward of the true vocal cords. The superior parts, sometimes called the *vestibule*, is broad and triangular in shape; the inferior part of the cavity is at first elliptical and lower down is circular, becoming continuous with the tube of the trachea. The—

Glottis or Rima Glottidis,—is a narrow chink or interval between the inferior vocal cords, formed by the projection into the cavity of the larynx of these cords and the thyro-arytenoidei muscles. Its greatest

length is less than an inch, its greatest breadth about half an inch. Its form is a narrow fissure of varying size.

Superior or False Vocal Cords (5),—contain the superior thyro-arytenoid ligaments, extend from the angle of the thyroid cartilage around to the anterior surfaces of the arytenoids, and consist of two folds of mucous membrane, each having a free crescentic margin.

Inferior or True Vocal Cords (9),—contain the inferior thyro-arytenoid ligaments, extend from the angle of the thyroid cartilage around to the anterior angles of the bases of the arytenoids, and consist of two thin layers of mucous membrane covering the ligaments named, each having the thyro-arytenoideus muscle external and parallel to it.

Ventricle of the Larynx (7),—is an oblong fossa on each side of the larynx, between the true and false vocal cords, leading up to the sacculus laryngis by a narrow opening.

Sacculus Laryngis or Laryngeal Pouch,—is a membranous sac, placed between the superior vocal cord and the thyroid cartilage. It is of conical shape, and contains 60 or 70 small mucous glands which secrete a fluid for the lubrication of the true vocal cord. The sacculus is covered in by the aryteno-epiglottideus inferior muscle internally, and by the thyro-epiglottideus externally, both muscles compressing it to discharge its contents. The Sacculus Laryngis is also called the Sinus of Morgagni, and the lower part of the ventricle is sometimes named the Sac of Hilton.

Epithelium,—is stratified squamous epithelium over the true vocal cords, the upper part of the aryteno-epiglottidean folds, and the upper half of the posterior surface of the epiglottis; over all the rest of the larynx, the lining mucous membrane is covered by columnar ciliated cells.

Muscles of the Larynx are 8 in number, 5 of which are the muscles of the vocal cords and rima glottidis, and 3 are connected with the epiglottis. The former are the—

Crico-thyroid.

Arytenoideus.

Crico-arytenoideus Posticus.

Thyro-arytenoideus.

Crico-arytenoideus Lateralis.

Muscles of the Epiglottis are the-

Thyro-epiglottideus. Aryteno-epiglottideus Superior and Inferior.

These muscles are described at page 84.

Vessels of the Larynx. The Arteries are the Superior Laryngeal and Crico-thyroid branches of the superior thyroid, from the external carotid; and the Inferior Laryngeal branch of the inferior thyroid from the thyroid axis. The—

Veins,—open into the internal jugular and the innominate vein.

Lymphatics,—open into glands near the bifurcation of the common carotid artery, and others in front of the crico-thyroid membrane.

Nerves of the Larynx are the Superior and Recurrent Laryngeal branches of the pneumogastric, joined by filaments from the spinal accessory and the sympathetic. The—

Superior Laryngeal,—is the nerve of sensation. It enters the larynx by a hole in the thyro-hyoid membrane, and supplies the mucous membrane, and the crico-thyroid and arytenoideus muscles. It has the following branches, namely—

External Laryngeal.

Internal Laryngeal.

Recurrent Laryngeal,—is the motor nerve. It winds from before backwards, around the subclavian artery on the right side, around the arch of the aorta on the left side, and is distributed to all the laryngeal muscles except the crico-thyroid; giving off, in its course, cardiac, cesophageal, tracheal, and pharyngeal filaments, and finally anastomosing with the superior laryngeal nerve.

# THE TRACHEA AND BRONCHI.

The Trachea is a membrano-cartilaginous, cylindrical tube, about 4½ inches long, and ½ to 1 inch in diameter, beginning at the lower border of the larynx, opposite the 6th cervical vertebra, and ending opposite the 4th dorsal, by its bifurcation into the two bronchi. It is composed of a fibro-elastic membrane containing 16 to 20 imperfect cartilaginous rings, connected by muscular fibres. It is lined with mucous membrane covered with ciliated columnar epithelium, and furnished with racemose glands, the tracheal glands.

Anteriorly,—it is convex, and is covered from above downward by the—

Thymus Gland.

Arch of the Aorta.

Innominate Artery.

Left Carotid Artery.

Left Innominate Vein.

Isthmus of the Thyroid Gland.
Inferior Thyroid Veins.
Sterno-hyoid Muscle.
Sterno-thyroid Muscle.
Cervical Fascia.

Manubrium of the Sternum. Deep Cardiac Plexus.

Posteriorly,—it is flat, and in relation with the Œsophagus.

Laterally, -it is in relation with the-

Common Carotid Arteries. Recurrent Laryngeal Nerves.

Thyroid Gland, lateral lobes. Pleuræ.

Inferior Thyroid Arteries. Pneumogastric Nerves.

The Bronchi are two tubes similar in formation to the trachea, extending

from its bifurcation into the lungs, where they divide and subdivide into bronchial tubes, losing their rings at the 2d or 3d subdivision, whence plates of cartilage extend in their walls to their minuter ramifications. The—

Right Bronchus,—the widest, and the most horizontal, is about r inch long, has 6 to 8 rings, and divides into 2 main divisions, the eparterial branch, to the upper lobe, given off above the pulmonary artery, and the hyparterial branch, passing under the artery, to be divided into two branches, for the middle and lower lobes. The right bronchus lies behind the vena cava superior and the right auricle of the heart, having the right pulmonary artery at first below, then anterior to it, and the vena azygos major arching over it from behind forward.

Left Bronchus,—the narrowest and most oblique, is nearly 2 inches long, has 9 to 12 rings, and divides into 3 main divisions (though its lung has but 2 lobes). It passes beneath the arch of the aorta and in front of its descending portion, also in front of the cesophagus and the thoracic duct, having the left pulmonary artery above and in front of it.

Vessels and Nerves. The Arteries are the Tracheal, branches of the inferior thyroid, from the thyroid axis; and the Bronchial, from the thoracic aorta. The—

Veins,—open into the thyroid plexus and the bronchial veins.

Lymphatics,—terminate in the mediastinal glands.

Nerves,—are derived from the pneumogastric and its recurrent laryngeal branch, also from the sympathetic.

# THE PLEURÆ.

The Pleuræ are two delicate serous sacs, one surrounding each lung, and reflected over the pericardium, the diaphragm, and the inner surface of the thorax. The right sac is shorter, wider, and reaches higher into the neck than the left. The two sacs meet for a short space behind the middle of the sternum, at the approximation of the anterior borders of the lungs. The—

Pleura Pulmonalis, or Visceral Layer,—covers the lung, and invests that organ as far as its root.

Pleura Costalis, or Parietal Layer,—lines the inner surface of the parietes of the chest.

Cavity of the Pleura,—is the space between the two layers.

Ligamentum Latum Pulmonis, or Broad Ligament of the Lung,—is a triangular fold or reflection of pleura, which descends from the root of the lung posteriorly to the upper surface of the diaphragm.

The Mediastinum is the space between the two pleuræ in the median

line of the thorax, extending from the sternum to the vertebral column, and containing all the thoracic viscera except the lungs. The—

Superior Mediastinum,—lies above the upper level of the pericardium and contains the—

Origins of the Sterno-hyoid and Sterno-thyroid Muscles.

Lymphatic Glands.

Left Superior Intercostal Vein.

Anterior Mediastinum,—between the sternum and the pericardium, contains—

Areolar Tissue. Branches of Internal Mammary Artery.

Triangularis Sterni Muscle. Lymphatic Vessels and Glands. Middle Mediastinum.—contains the—

Heart and Pericardium. Bifurcation of the Trachea.

Ascending Aorta.

Pulmonary Arteries and Veins.

Superior Vena Cava, lower half.

Phrenic Nerves. Lymphatic Glands.

Posterior Mediastinum,—contains the—

### THE LUNGS.

The Lungs are the two essential organs of respiration contained in the cavity of the thorax, where they are separated from each other by the heart (1) and the other contents of the mediastinum. They are covered by the pleuræ, and are characterized by lightness (sp. gr. 0.345 to 0.746), sponginess, elasticity, and crepitation when pressed. They weigh together about 42 ounces, the right lung being the heaviest by about 2 ounces. At birth their color is a pinkish-white, becoming mottled as age advances by slate-colored patches, from the deposit of carbonaceous granules in the areolar tissue of the organ. The Right Lung is the largest and has 3 lobes; the Left Lung has 2 lobes. Each lung presents for examination an—

Apex,—situated in the neck, behind the interval between the two heads of the sterno-mastoid muscle, and rising about an inch above the

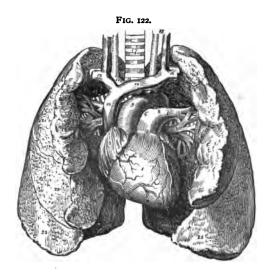

clavicle. It is in relation with the subclavian artery and the scaleni muscles.

Base,—is broad, concave, and directed obliquely downward and backward, resting on the upper convex surface of the diaphragm.

External Surface,—is convex, smooth, marked by the fissures, and corresponds in form to that of the thorax.

Inner Surface,—is concave, presents in front a depression for the heart and behind a deep fissure, the hilum, which gives attachment to the root of the lung.

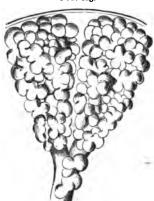

Root,—is where the bronchus (18), vessels (20), and nerves enter the

lung, bound together by areolar tissue. In front of the root is the phrenic nerve, behind it the pneumogastric nerve. Its chief structures are arranged in the following manner:—

Structure of the Lung. The lung has a serous coat (the pleura); a sub-serous, elastic areolar tissue, investing the entire organ, and extending inward between the lobules; and the parenchyma, or true lung-tissue, composed of—

Lobules,—each consisting of several air-cells or compartments, arranged around the termination of a bronchiole, and surrounded by 6 plexuses of pulmonary and bronchial arteries and veins, lymphatics and nerves. Each lobule is a miniature lung, pyramidal in form, with base outward, and about 1 inch in diameter. Fig. 123 shows 2 lobules.

Alveoli, or Air-cells,—are separated from each other by thin septa, are lined with pavement epithelium on a basement membrane, and vary in diameter from  $\frac{1}{200}$  to  $\frac{1}{10}$  inch.

# Vessels and Nerves of the Lungs.

The lungs are nourished by the bronchial arteries, and supplied with blood for oxygenation by the pulmonary arteries.

Bronchial Arteries,—are derived from the thoracic aorta.

Bronchial Veins,—open on the right side into the vena azygos major, on the left side into the superior intercostal vein.

Pulmonary Arteries (5, 6, 7),—are derived from the right heart.

Pulmonary Veins (20),—open by 4 large orifices into the left auricle of the heart, carrying oxygenated blood from the lungs to the left heart.

Lymphatics,—terminate in the bronchial glands, at the root of the lung.

Nerves,—are branches from the pneumogastric and the sympathetic, forming the anterior and posterior pulmonary plexuses, from which filaments are distributed to each lobule.

## THE THYROID AND THYMUS GLANDS.

The Thyroid and Thymus Glands belong to the ductless glands, (see 1ge 309), and have no connection with the function of respiration. From

their situation in the neck, they are usually described in connection with the larynx, trachea and lungs.

### THE THYROID GLAND.

The Thyroid Gland is a bi-lobed organ, about 3 inches in length, situated on the sides of the upper rings of the trachea, and consisting of minute closed vesicles containing a yellow glairy fluid, surrounded by a dense plexus of capillaries, and connected together by areolar tissue. It is invested by a thin capsule of connective tissue, which projects into its substance, and imperfectly divides it into irregular masses. Its—

Isthmus,—connects the lower third of each lobe together, passing in front of the trachea. It is occasionally absent.

Pyramid,—is a third lobe, which sometimes arises from the left lobe, or from the left upper border of the isthmus.

Levator Glandulæ Thyroideæ,—are muscular bands occasionally found extending from the body of the hyoid bone to the isthmus of the gland or its pyramid.

Vessels and Nerves. The Arteries are the Superior Thyroid, from the external carotid, and the Inferior Thyroid, from the thyroid axis; they are large, and anastomose freely. A third branch, the Thyroidea Ima, from the innominate or the arch of the aorta, is sometimes found, ascending along the front of the trachea. The—

Veins,—form a plexus on the front of the gland, from which arise the superior, middle, and inferior Thyroid Veins, the two former terminating in the internal jugular, the latter in the innominate vein.

Lymphatics,—terminate in the thoracic and right lymphatic ducts.

Nerves,—are derived from the middle and inferior ganglia of the sympathetic.

Parathyroids are small brownish-red bodies, averaging about  $\frac{1}{4}$  inch in diameter, situated in or near the thyroid gland, from which they differ in structure, being composed of masses of cells arranged in a more or less columnar fashion, with numerous intervening capillaries.

### THE THYMUS GLAND.

The Thymus Gland is a temporary organ, attaining its full size about the age of 2 years, then being about 2 inches long,  $1\frac{1}{2}$  inch broad, and 3 lines thick. It subsequently atrophies, and has almost disappeared at puberty. It is situated in the superior mediastinum and in the neck, extending from the level of the 4th costal cartilage to the lower border of the thyroid gland. In the mediastinum it rests upon the pericardium, and is separated

by the thoracic fascia from the arch of the aorta and the great vessels. In the neck it lies on the front and sides of the trachea, behind the sternohyoid and sterno-thyroid muscles.

Structure. The Thymus gland consists of two lateral lobes (sometimes three), together forming a pyramidal mass. It is surrounded by a fibrous capsule and is divided by trabeculæ into primary lobules and secondary follicles, which consist of meshes of delicate retiform tissue closely packed with lymphoid cells, and pervaded with capillaries. The central, medullary portion contains few lymphoid cells, but many granular cells and concentric corpuscles.

Vessels and Nerves. The Arteries are derived from the internal mammary and the superior and inferior thyroid arteries. The—

Veins,—open into the left innominate and the thyroid veins.

Lymphatics,—consist of intralobular and interlobular plexuses, and are said to open into the internal jugular vein.

Nerves,—are very minute and are derived from the pneumogastric and the sympathetic.

# THE URINARY ORGANS.

### THE KIDNEYS.

The Kidneys are two organs, situated in the back part of the abdominal cavity, one on each side of the vertebral column, behind the peritoneum, extending from the 11th and 12th ribs to within 2 inches of the crest of the ileum, the right kidney being a little lower than the left one. Each kidney is about 4 inches by 2 by 1, in the male adult weighs from  $4\frac{1}{2}$  to 6 oz.; and presents on its inner concave border the—

Hilum,—a fissure leading into the sinus or cavity of the organ, and permitting the passage of the vessels, nerves, and ureter, arranged in the following order, from before backward, the renal vein, renal artery, ureter, VAU.

Relations of the Kidneys. They are partially covered by peritoneum on their anterior surface, but not at all posteriorly. They are surrounded by a mass of fat and areolar tissue, and have the following relations:—

Anterior Surface of the Right Kidney,—is in relation with the right lobe of the liver, the descending duodenum, and the ascending colon.

Anterior Surface of the Left Kidney,—with the tail of the pancreas, the descending colon, and part of the spleen.

Posterior Surface,—with the crus of the diaphragm, 11th and 12th ribs, psoas magnus, quadratus lumborum, and the aponeurosis of the transversalis muscle.

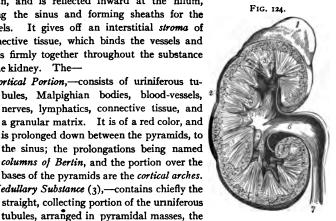

Superior Extremity,—is capped by the supra-renal capsule (1).

Injerior Extremity,—extends to within 2 inches of the crest of the ilium.

General Structure of the Kidney is shown by a vertical section from its convex to its concave border, and is seen to consist of a central cavity or sinus, surrounded except on one side by the kidney substance proper. The latter is divided into a cortical portion externally, and a medullary portion internally, the medullary being arranged in pyramidal masses, whose apices project into the central cavity. A dense, fibrous capsule invests the

organ, and is reflected inward at the hilum, lining the sinus and forming sheaths for the It gives off an interstitial stroma of connective tissue, which binds the vessels and tubes firmly together throughout the substance of the kidney. The-

Cortical Portion, -consists of uriniferous tubules, Malpighian bodies, blood-vessels, nerves, lymphatics, connective tissue, and a granular matrix. It is of a red color, and is prolonged down between the pyramids, to the sinus; the prolongations being named columns of Bertin, and the portion over the bases of the pyramids are the cortical arches. Medullary Substance (3),—contains chiefly the

pyramids of Malpighi, the apices of which project into the sinus.

Sinus,—receives the pelvis (6) of the ureter (7), and is divided into 3 infundibula (5), and they into 7 to 13 calices, into which open the orifices of the uriniferous tubules, 1000 on each papilla or apex of a pyramid.

Minute Structure of the Kidney commences in the cortical substance of the organ as the Malpighian bodies, small round masses of deep-red color, averaging about  $\frac{1}{120}$ th inch in diameter, and each consisting of a central glomerulus of vessels and a membranous envelope, the latter being the commencement of a uriniferous tubule. The-

Malpighian Tuft,—or vascular glomerulus, is a network of convoluted capillary blood-vessels, beginning by the afferent vessel and ending in

the efferent vessel, which are the respective radicles of some of the branches of the renal artery (a) and the renal vein (v).

FIG. 125.

Bowman's Capsule (c),—surrounding the glomerulus, is the dilated extremity of a uriniferous tubule (d), and is lined on its inner surface by a layer of squamous epithelial cells, on a delicate supporting membrane, closely surrounding the convolutions of the glomerulus and dipping in between them.

The Tubuli Uriniferi, or Uriniferous Tubules, begin at the capsule of Bowman in the Malpighian bodies, and open into the sinus of the kidney by orifices on the surface of the papillæ. their course they leave the cortical portion, enter the medullary portion, return to the cortical and

again to the medullary, in which they continue to their termination. In their course they become first convoluted, then spiral, then looped, again spiral and convoluted, curved and finally straight; and have received the following names:-

Proximal Convoluted Tube,—the first portion, below the neck at Bowman's capsule, in the cortical zone. Epithelium lining the tube is polyhedral and of striated appearance.

Spiral Tube of Schachowa,—in the cortical zone. Epithelium potyhedral and striated.

Henle's Loop,—in the medullary zone, consists of a descending limb, a loop, and an ascending limb, the latter becoming spiral as it ascends into the cortical zone. Epithelium flat in the descending limb, polyhedral and striated in the ascending one.

Irregular Tubule,—in the cortical zone. Epithelium angular and striated. Distal Convoluted Tubule,—in the cortical zone. Epithelium polyhedral. Curved Tube,—in the cortical zone. Epithelium varied, angular, spindleshaped, polyhedral.

Straight or Collecting Tube,—partly in the cortical zone, descends through the medullary portion and joins with others, forming the pyramids of Ferrein (apices outward) in the cortical zone, and the pyramids of Malpighi (apices inward) in the medullary substance. Epithelium more or less columnar.

Connective Tissue or Stroma,—binds the tubules firmly together.

Arteries of the Kidney arise from the renal artery, a large branch of

the abdominal aorta. It divides into 4 or 5 branches, which enter the kidney at the hilum, giving off small branches to the supra-renal capsules, the ureter, etc. These again divide and end in the—

Arteriæ Propriæ Renales,—the renal arteries proper, which enter the kidney substance in the columns of Bertin (see page 321), form arterial arches over the bases of the pyramids, and divide into ascending and descending branches. The—

Ascending or Interlobular Branches,—pass to the capsule and end in the capillary network of that part of the cortex, giving off in their course the afferent vessels to the Malpighian tufts, (see page 321).

Descending or Arteriolæ Rectæ,—supply the medullary pyramids and end at their apices in the venous plexuses there situated.

Veins of the Kidney arise from 3 sources,—the stellate veins beneath the capsule of the organ, the venous radicles in the Malpighian tufts, and the venous plexuses at the apices of the pyramids of Malpighi. Those from the stellate plexuses on the surface of the kidney join together, forming the—

Interlobular Veins,—which pass inward between the pyramids of Ferrein, receive branches from the plexuses on the convoluted uriniferous tubes, and join with the venæ rectæ from the apices of the pyramids of Malpighi, to form the—

Venæ Propriæ Renales,—the renal veins proper, accompany the arteries of the same name, receive the efferent vessels from the Malpighian bodies adjacent, and join with corresponding veins in the sinus to form the—

Renal Vein,—emerges at the hilum and opens into the inferior vena cava; the left vein being longer than the right, having to cross in front of the abdominal aorta.

Nerves of the Kidney are derived from the hepatic plexus, which is formed by branches from the solar plexus, the aortic plexus, the semilunar ganglion, and the lesser and smallest splanchnic nerves. They have small ganglia upon them, and communicate with the spermatic plexus.

Lymphatics consist of a superficial and a deep set, and terminate in the lumbar glands.

#### THE URETERS.

The Ureter, the excretory duct of the kidney, is a musculo-membranous tube, which conducts the urine from the kidney to the bladder. It commences within the sinus of the kidney by 7 to 13 short tubes or calices, which encircle the apices of the pyramids of Malpighi, and converge into

2 or 3 tubular divisions or *injundibula*, these by their junction forming the *pelvis* or upper dilated extremity of the duct. The—

Ureter Proper,—begins at the lower end of the pelvis, is about 16 inches long, and of the diameter of a small goose-quill. It descends, through the lumbar region of the abdomen and the pelvic cavity, to the base of the bladder, and opens into the cavity of that organ about 2 inches from its fellow.

Course of the Ureter. In its course the ureter passes obliquely downward and inward through the lumbar region, and downward, inward and forward through the pelvic cavity, enters the posterior false ligament of the bladder, passes obliquely between the muscular and mucous coats of that organ for nearly an inch, and ends by a constricted orifice at one of the posterior angles of the trigone at the base of the bladder.

Relations of the Ureter. The junction of the renal pelvis and the ureter proper is opposite the spinous process of the first lumbar vertebra, about 2 inches from the middle line of the back. The ureter lies upon the psoas muscle and behind the peritoneum; behind the ileum on the right side and the sigmoid flexure of the colon on the left side. It crosses the common or the external iliac artery; and is crossed by the spermatic vessels, and the branches of the mesenteric arteries, also by the vas deferens in the male. The right ureter lies close to the outer side of the inferior vena cava. In the female the ureters pass along the sides of the neck of the uterus and the upper part of the vagina, and beneath the root of the broad ligament.

Structure of the Ureter. It is composed of 3 coats,—fibrous, muscular, and mucous. The *fibrous coat* is continuous with the capsule of the kidney and with the fibrous structure of the bladder. The—

Muscular Coat,—consists of longitudinal fibres externally, and circular fibres internally. A third layer, consisting of longitudinal fibres, is found internal to the circular layer, in the neighborhood of the bladder.

Mucous Coat,—is prolonged over the papillæ of the kidney, and is continuous with the mucous lining of the bladder. Its epithelium resembles that of the bladder, and is known as transitional epithelium, consisting of 3 layers of cells, the innermost of which are quadrilateral in shape.

Vessels and Nerves. The Arteries of the ureter are branches from the renal, spermatic, internal iliac, and inferior vesical. The Nerves are derived from the inferior mesenteric, spermatic, and pelvic plexuses.

### THE SUPRA-RENAL CAPSULES.

The Supra-renal Capsules are properly classed with the ductless glands, (see page 309). They are two small, yellowish bodies, situated one above each kidney, behind the peritoneum, and in the posterior portion of the abdomen. They vary in size in different individuals, but are usually 1½ inch long and wide, and from 2 to 3 lines in thickness. Each capsule has a small furrow, the hilum, on its anterior surface, in which the vessels enter the organ, and in structure consists of a—

Fibrous Capsule,—which is very thin, closely adherent, and sends numerous septa inward.

Cortical Substance,—composed of columnar masses of polyhedral cells, held together in layers by a fibrous stroma.

Medullary Substance,—is darker than the cortical portion, and pulpy. It consists of granular cells, supported by a delicate stroma, and believed by some anatomists to be prolonged into the nerve fibres of a very intricate plexus.

Relations of the Supra-renal Capsules. Their surface is surrounded by areolar tissue containing much fat; their bases rest on the upper front parts of the kidneys, their posterior surfaces on the crura of the diaphragm, about the level of the 10th dorsal vertebra. The—

Anterior Surface,—of the right capsule is covered by the liver; that of the left one by the spleen and pancreas.

Superior Surface,—of each is in relation internally with the great splanchnic nerve and semilunar ganglion.

Vessels and Nerves. The Arteries are the Supra-renal branches of the aorta, renal, and phrenic arteries, forming a dense capillary plexus in the cortical portion of the organ.

Veins,—of each open into a single trunk, the Supra renal Vein, which on the right side of the body empties into the inferior vena cava, on the left side into the left renal vein.

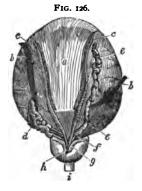

Lymphatics,—open into the lumbar glands.

Nerves,—are derived from the solar and renal plexuses, with some filaments from the phrenic and pneumogastric nerves, forming a complicated network in the medullary substance of the organ, and having numerous small ganglia developed upon them.

### THE BLADDER.

The Bladder, the reservoir for the urine, is a musculo-membranous sac, situated in the anterior portion of the pelvis, behind the pubes, and in

front of the rectum in the male, in front of the cervix uteri and vagina in the female. When empty and contracted, or when slightly distended, it is contained in the pelvic cavity; when greatly distended it is ovoid in shape, and rises into the abdominal cavity, often extending nearly as high as the

umbilicus. When moderately distended it measures about 5 by 3 inches, and holds about a pint. The—

Summit,—is connected to the umbilicus by the urachus and the obliterated hypogastric arteries of the fœtus, forming three fibrous cords, the Superior Ligament of the bladder.

Superior Surface,—is free, and is covered by peritoneum.

Anterior Surface,—is partly covered by peritoneum above, and is in relation below with the internal obturator muscles, the recto-vesical fascia, and the anterior true ligaments of the bladder.

Posterior Surface,—is covered by peritoneum, and is in relation with the rectum in the male, with the uterus and upper part of the vagina in the female.

Lateral Surfaces,—are partly covered by peritoneum behind and above; each is crossed obliquely by the obliterated hypogastric artery and the vas deferens (c), the first passing from below forward, the latter from below backward.

Fundus or Base,—is partly covered by peritoneum, and rests on the second portion of the rectum in the male, on the lower part of the cervix uteri and adherent to the anterior wall of the vagina in the female.

Cervix or Neck,—is constricted and continuous with the urethra (i). It is surrounded in the male by the prostate gland (h), and is directed downward and forward.

Ligaments of the Bladder are 10 in number, of which 5 are true ligaments, and 5 are false ligaments, being formed by folds of peritoneum. The true ligaments are the—

Anterior or Pubo-prostatic, 2,—are formed by the recto-vesical fascia, and extend from the neck of the bladder, over the prostate gland, to the back of the pubic bone.

Lateral, 2,—also formed by the recto-vesical fascia, are attached to the sides of the base of the bladder, and the prostate gland.

Urachus,—the superior ligament, connects the summit of the bladder with the umbilicus. It is the obliterated remains of a canal, which in the embryo connects the bladder with the allantois, and is situated between the two obliterated hypogastric arteries.

False Ligaments, folds of peritoneum, are the-

Posterior False Ligaments, 2,—pass from the postero-lateral parts of the bladder, to the sides of the rectum in the male, to the sides of the uterus in the female.

Lateral False Ligaments, 2,—from the iliac fossæ and lateral walls of the pelvis to the sides of the bladder.

Superior, or Suspensory Ligament,—from the summit of the bladder to the umbilicus, being peritoneum carried off from the bladder by the urachus and the obliterated hypogastric arteries.

Interior of the Bladder is lined by mucous membrane, which forms folds or rugæ when the viscus is empty, being loosely connected to the muscular coat, except at the trigone and the uvula, where it is closely adherent. The floor of the bladder presents the—

Trigonum Vesicæ, or Vesical Trigone (1 Fig. 127),—a pale-colored, triangular space, extending from the urethral opening in front to a line connecting the orifices of the ureters behind; and characterized by its smooth surface and the intimate adhesion between its mucous and muscular coats.

Uvula Vesicæ (3 Fig. 127),—is a small elevation of mucous membrane projecting from the floor of the bladder into the urethral orifice. It is said to be lifted by the anterior fibres of the levator ani muscle.

Orifices of the Ureters (2 Fig. 127),—about 2 inches apart, at the base of the trigone, and 1½ inch from the urethral opening.

Structure of the Bladder. The bladder has 4 coats,—serous or peritoneal, muscular, sub-mucous, and mucous. The peritoneal coat is a partial one, investing only the superior and posterior surfaces, and the upper portion of the lateral surfaces. The—

Muscular Coat,—consists of unstriped muscular fibres, arranged in 3 layers; an external layer, chiefly longitudinal, the so-called detrusor urinæ muscle; a middle layer, mostly circular, and forming a sphincter vesicæ around the neck; and an internal layer, chiefly longitudinal.

Muscles of the Ureters,—are two bands of oblique fibres, extending from behind the orifices of the ureters to the middle lobe of the prostate gland.

Sub-mucous Coat,—is a layer of areolar tissue, connecting the muscular with the mucous coat.

Mucous Coat,—is thin, smooth, of a pale rose color, and is continuous with the lining membrane of the ureters and the urethra. Its epithelium is of the transitional variety, consisting of an inner layer of polyhedral, flattened, nucleated cells; beneath which are two layers of clubshaped and spindle-shaped cells, wedged together. It contains no mucous glands.

Vessels and Nerves. The Arteries of the bladder are the superior, middle, and inferior Vesical in the male, with additional branches from the uterine and vaginal in the female; all from the anterior trunk of the internal iliac. The—

Veins,—form a plexus around the neck, sides, and base of the bladder, and terminate in the internal iliac vein.

Lymphatics,—terminate in the internal iliac glands.

Nerves,—are derived from the pelvic plexus to the upper part of the organ, from the 3rd and 4th sacral nerves to its base and neck.

### THE MALE URETHRA.

The Urethra is the urinary canal from the neck of the bladder to the meatus urinarius; in the male it is chiefly within the penis, is from 8 to 9 inches in length, and is divided into three parts,—the prostatic, membranous, and spongy portions of the urethra.

The Prostatic Portion of the Urethra is that part of the canal which pierces the prostate gland (4), is about 1½ inch in length, of spindle shape, and the widest and most dilatable part of the urethra. Its floor presents the—

Verumontanum, or Caput Gallinaginis (6),—an elevation of the mucous membrane and its adjacent tissue,  $\frac{3}{2}$  inch long, and supposed to contain muscular and erectile tissue.

Prostatic Sinus (7),—one on each side of the verumontanum, containing the orifices of the prostatic ducts.

Sinus Pocularis, or Uterus Masculinus (5),—is a small cul-de-sac situated at the front part of the verumontanum. It extends for 1 inch upward and backward into the prostate gland, beneath its middle lobe.

Orifices of the Ejaculatory Ducts (8),—open on the margins of the sinus pocularis.

The Membranous Portion (9) is  $\frac{3}{4}$  inch long above, and  $\frac{1}{2}$  inch along its floor, being that part of the canal lying between the superior and inferior layers of the triangular ligament of the perinæum. Its walls are very thin, and almost destitute of erectile tissue. It is surrounded by the compressor

urethræ muscle, and except the orifice, is the narrowest part of the urethral

On its sides are the-Ducts of Cowper's Glands (11), -on their way to open into the bulb of the urethra.

The Spongy Portion (16) is about 6 inches long, and has two dilatations, one at each end, named respectively the Bulb and the Fossa Navicularis. The-

Bulb of the Urethra (13),is the upper end of the spongy portion, projects backward for 1 inch, and contains the orifices (15) of the ducts of Cowper's glands.

Fossa Navicularis,-is the lower dilatation of the urethra, and is situated within the glans penis.

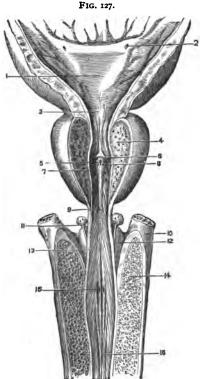

Lacuna Magna,-the largest of several orifices of mucous follicles, situated on the roof of the fossa navicularis.

Glands of Littré, -are numerous mucous glands and follicles, opening into the

urethral canal, their orifices being directed forward.

Meatus Urinarius,—the external orifice; is the most contracted portion of the urethra, and presents a vertical slit, about 3 lines long, bounded laterally by two small labia.

Structure of the Urethra. It is composed of a continuous mucous membrane, continuous with the mucous lining of the bladder, ureters, and kidneys, and prolonged into the ducts opening into the urethra. The mucous membrane is supported by a submucous tissue, which connects it with the various structures through which it passes.

Submucous Tissue,—consists of a vascular erectile layer, outside which is a circular layer of unstriped muscular fibres.

Voluntary Muscles of the Urethra,—are the compressor urethræ and the accelerator urinæ, described on page 96.

Epithelium,—is of the columnar variety, except near the meatus where it is squamous.

## THE FEMALE URETHRA.

The Urethra in the female is only about 1½ inch long, imbedded in the anterior wall of the vagina, perforating the triangular ligament, and surrounded by fibres of the compressor urethræ muscle. Its diameter is about ¼ inch, but it is capable of considerable dilatation, being surrounded by softer structures than those around the male urethra. The—

Meatus Urinarius,—is situated directly in front of the vaginal opening and about an inch behind the glans clitoridis.

# ORGANS OF GENERATION.

# THE MALE ORGANS OF GENERATION.

## THE URETHRAL GLANDS.

The Prostate Gland is a musculo-glandular organ, which surrounds the neck of the male bladder and the beginning of the male urethra. It is situated in the pelvic cavity, behind the lower part of the symphysis pubis, and above the deep layer of the triangular ligament, its posterior surface resting on the rectum. It is perforated by the urethra and the common seminal ducts, but its own ducts open into the prostatic portion of the urethra. It measures about  $1\frac{1}{2}$  inch by  $1\frac{1}{4}$  inch by 1 inch, weighs about  $\frac{3}{4}$  oz., resembles a horse-chestnut in size and shape, and consists of three lobes, two being lateral and of equal size, the third or middle lobe being a small prominence situated in the notch between the lateral lobes. Its—

Position,—is maintained by the anterior or pubo-prostatic ligaments of the bladder, the deep layer of the triangular ligament, and the anterior portions of the levator ani muscles.

Structure,—is glandular substance arranged in follicular pouches, and dense muscular tissue, the whole being invested by a firm fibrous capsule, which gives off thin trabeculæ into the substance of the gland.

Ducts,—are 12 to 20 in number, lined by columnar epithelium, and open on the floor of the prostatic portion of the urethra.

Arteries,—are derived from the internal pudic, vesical and hæmorrhoidal arteries.

Veins,—terminate in the internal iliac vein.

Nerves,—are branches from the pelvic plexus.

Cowper's Glands are two small, rounded bodies, about the size of peas, situated between the two layers of the triangular ligament, one on each side of the membranous portion of the urethra, close above the bulb, and enclosed by the transverse fibres of the compressor urethræ muscle. The—

Excretory Duct,—of each gland opens by a minute orifice on the floor of the bulbous part of the spongy portion of the urethra, after traversing the wall of the urethra for about one inch, beneath its mucous coat.

## THE PENIS.

The Penis is composed of a mass of erectile tissue enclosed in three cylindrical compartments, each surrounded by a fibrous sheath which is prolonged inward, forming numerous bands or trabeculæ, which divide the compartments into a number of spaces. The compartments are the two corpora cavernosa and the corpus spongiosum (6), the latter lying between and beneath the former, like the ramrod of a double-barreled gun. The—

Erectile Tissue,—is lodged in the interspaces between the trabeculæ of the fibrous structure, and consists of an intricate venous plexus, supplied by afferent arteries and emptied by efferent veins.

The Corpora Cavernosa lie side by side, forming the upper and lateral parts of the penis. They are joined together along their anterior three-fourths, their posterior one-fourth forming the *Crura*, which arise from the

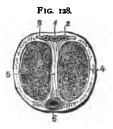

tuberosities of the ischia and their descending rami, and meet beneath the symphysis pubis, forming two grooves, one above for the dorsal vessels (1), and nerves (3), the inferior one for the corpus spongiosum (6).

Bulb of the Corpus Cavernosum,—is a slight enlargement on each crus, near its junction with its fellow.

Suspensory Ligament,—a fibrous membrane which connects the root of the organ to the symphysis pubis.

The Corpus Spongiosum (6) is an erectile tube lying in the inferior groove between the two corpora cavernosa, having within it the urethra,

and expanded at both ends to form the glans penis and the bulb. It is composed of trabecular (band-like) structure, derived from a fibrous sheath, and containing erectile tissue. The—

Bulb of the Corpus Spongiosum,—receives the urethra and is surrounded by the accelerator urinæ muscle.

Glans Penis,—is the external expansion of the corpus spongiosum, and covers by its base the ends of the two corpora cavernosa. Its base presents a rounded border, called the *corona glandis*, behind which is a deep sulcus, the *cervix*.

Glands of Tyson,—small lenticular sebaceous glands opening on the corona and cervix of the glans, and secreting an odorous sebaceous matter, the smegma, which decomposes readily.

Meatus Urinarius,—the external orifice of the urethra, is situated at the summit of the glans penis.

Prepuce,—a prolongation of the integument of the penis, covering or partly covering the glans penis.

Frænum Præputii,—a fold of mucous membrane lying along the raphé of the glans penis, and connecting the prepuce with the glans.

Vessels and Nerves. The Arteries are branches of the internal pudic, named as follows: the artery of the bulb, to the bulb of the corpus spongiosum; the arteries of the corpora cavernosa, to that structure; and the dorsal artery of the penis, to the integument and fibrous sheath of the corpora cavernosa, the glans and prepuce. The—

Helicine Arteries,—are vine-like branches, which project into the cavernous spaces, and are most abundant in the back part of the corpora cavernosa.

Veins,—empty into the dorsal vein of the penis and the prostatic venous plexus. They form intricate and well developed plexuses in the erectile tissue.

Lymphatics,—the superficial terminate in the inguinal glands; the deep join the deep lymphatics of the pelvis.

Nerves,—are derived from the internal pudic nerve, and the pelvic plexus of the sympathetic.

### THE TESTES.

The Testes or Testicles are the glandular organs which secrete the seminal fluid,—two oval bodies suspended obliquely in the scrotum by the spermatic cords, each measuring about an inch in diameter, and weighing \(\frac{3}{4}\) oz. to an ounce. Their coverings, from without inward, are 6 in number, as follows:—

Dartos (5),—the vascular tunic. Scrotum, (see Fig. 130).

Intercolumnar Fascia,—the external spermatic fascia (6, Fig. 130).

Cremasteric Fascia (7, Fig. 130),—muscular fibres, the cremaster muscle, derived from the lower border of the internal oblique muscle.

Infundibuliform Fascia (9, Fig. 130),—internal spermatic fascia, or fascia propria; a continuation downward of the transversalis fascia.

Tunica Vaginalis,—the serous covering, originally a process of the peritoneum, (see below).

The Scrotum is a cutaneous pouch, consisting of 2 layers—the integument and the *Dartos*; the latter being a contractile vascular tunic, continuous with the superficial fascia of the thighs and perinæum, and forming a septum in the scrotum between the two cavities for the testes.

The Epididymis is an appendix to the testicle, lying along its posterior border, and consists of a single duct about 20 feet in length when unraveled, but which is wound upon itself so as to occupy a very small space. The—

Globus Major (7),—is formed by the coni vasculosi, or efferent ducts (6) of the testis, which therein open into the single duct which forms the epididymis.

Body (8),—is formed by the convolutions of the tube, held together by fine connective tissue.

Globus Minor (9),—the lower expanded portion, similarly formed, and connected to the testis by cellular tissue.

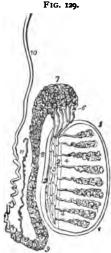

Vas Aberrans (11),—a narrow tube, sometimes found opening into the canal of the epididymis near its lower end, and ending in a blind extremity.

Hydatids of Morgagni,—small pedunculated bodies, found attached to the epididymis or to the upper end of the testicle. One of them is believed to be the remains of the duct of Müller.

Tunics of the Testis are 3 in number,—the tunica vaginalis, or serous covering, externally; the tunica albuginea, or fibrous covering, in the middle; and the tunica vasculosa, or pia mater testis, internally. The—

Tunica Vaginalis, the serous covering,—has a visceral layer (11) (tunica vaginalis propria) and a parietal layer (8) (tunica vaginalis reflexa).

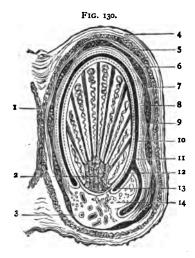

Originally a part of the peritoneum, its upper end becomes oblit-

the layers being the cavity (10) of the tunica vaginalis. It forms a pouch, the digital jossa (13), between the epididymis and the testicle. Tunica Albuginea (12), the fibrous covering,—consists of white fibrous

erated, and the lower end remains as a closed sac, the space between

Tunica Albuginea (12), the norous covering,—consists of white indrous tissue, and forms an incomplete vertical septum within the gland, the

corpus Highmorianum or mediastinum testis (2), from which fibrous bands (trabeculæ) cross the gland, dividing its interior into spaces for the lobules of the organ.

Tunica Vasculosa, the vascular covering,—lies beneath the preceding, and lines the septa in the interior of the gland. It consists of a plexus of bloodvessels, held together by a delicate areolar tissue.

Structure of the Testis. The glandular structure consists of 250 to 400 lobules, which are each contained in one of the spaces formed by the trabeculæ, and formed of 1 to 3 or more mi-

nute, convoluted tubes, the *tubuli seminiferi*. The latter consist of a basement membrane, lined by several layers of cells, from which the spermatozoa are developed. In the apices of the lobules the tubuli become straight, and join to form 20 or 30 ducts, the—

Vasa Recta (4, Fig. 129),—are each about  $\frac{1}{50}$  inch in diameter; then enter the mediastinum, passing upward and backward, and forming the—

Rete Testis (5),—a network of anastomosing tubes or channels in the fibrous stroma of the mediastinum; they end in the—

Vasa Efferentia (6),—12 to 20 ducts, which perforate the tunica albuginea of the testis, and form a number of conical masses, the *coni vasculosi*, which together constitute the *globus major* (7) of the Epididymis, (see Fig. 129).

Descent of the Testes. In early feetal life the testes are situated in the abdominal cavity, just below the kidneys, and are connected to the dartos of the scrotum and the tissues about the inguinal canal by a cord named regulernaculum testis, which prevents the testicle rising with the growth

of the fœtus, and the testicle is drawn first into the inguinal canal, and eventually into the scrotum, the cord itself becoming shortened as development proceeds. The descent begins about the commencement of the 5th month; during the 7th month the testicle enters the inguinal canal, and ordinarily arrives in the scrotum by the end of the 8th month. A process of peritoneum is carried down in front of the testis; which process, by obliteration of the canal, becomes a separate structure, the tunica vaginalis. The structures of the inguinal canal are also brought down with the testicle, and constitute some of its coverings.

Vessels and Nerves. The Arteries are the Spermatic, from the aorta to the testicle itself; its coverings are supplied by the superficial and deep External Pudic from the femoral, the superficial Perineal branch of the Internal Pudic from the internal iliac, and the Cremasteric branch of the epigastric from the external iliac.

Veins.—The spermatic veins emerge at the back of the testis, receive branches from the epididymis, and unite into the convoluted pampini-jorm plexus, which forms the chief mass of the spermatic cord. From this plexus 3 or 4 veins arise, they unite into 2, and these join into a single trunk, which on the right side empties into the inferior vena cava, on the left side into the left renal vein.

Lymphatics,—of the testis terminate in the lumbar glands; those of its coverings in the inguinal glands.

Nerves,—of the testes are derived from the spermatic plexus, joined by filaments from the pelvic plexus; those of their coverings are the ilioinguinal branch of the lumbar plexus, the superficial perineal branches of the internal pudic, the inferior pudendal branch of the small sciatic, and the genital branch of the genito-crural.

### APPENDAGES OF THE TESTES.

The Vas Deferens is the continuation of the epididymis, and the excretory duct of the testicle. Beginning at the globus minor it ascends along the back of the spermatic cord to the inguinal canal, and enters the abdominal cavity through the internal abdominal ring. It curves around the outer side of the epigastric artery, crosses the external iliac vessels, and descends into the pelvis at the side of the bladder, crossing to the inner side of the ureter and the inner border of the vesicula seminalis. At the base of the prostate gland it joins the duct of the seminal vesicle to form the ejaculatory duct. The vas deferens is about 2 feet long, and has a canal of only half a line in diameter. Its walls are very dense, making

it feel like a piece of wire or whip-cord when grasped between the fingers. In structure it consists of three coats, the-

Areolar Coat,—externally, beneath which is the—

Muscular Coat,-in 2 layers of unstriped fibre, the outer longitudinal, and the inner circular; but a third longitudinal layer is found at the commencement of the vas, internal to the circular layer.

Mucous Coat,—internally, is pale and in longitudinal folds; its epithelium is columnar.

Artery of the Vas Deferens,—a branch of the superior vesical, ramifies on its coats and anastomoses with the spermatic artery.

The Spermatic Cord extends from the internal abdominal ring to the globus minor of the epididymis, and is about 4 inches long. At the external abdominal ring it rests upon Poupart's ligament, having the aponeurosis of the external oblique muscle in front, and the conjoined tendon behind it. It is composed of arteries, veins, lymphatics, nerves, and the vas deferens, bound together by areolar tissue, and invested by the layers brought down by the descent of the testicle. The vessels, etc., composing the spermatic cord, are 13 in number, and are named as follows: the-

Vas Deferens. Spermatic Plexus of Nerves. Spermatic Artery. Branch of the Ilio-inguinal Nerve. Cremasteric Artery. Branch of the Genito-crural Nerve. Vas Aberrans.

Artery of the Vas Deferens.

Deferential Veins. Obliterated Processus Vaginalis of

Spermatic Veins. the peritoneum. Internal Cremaster Muscle. Lymphatics.

Coverings of the Cord, from within outward, are the-Infundibuliform Fascia, from the transversalis fascia. Cremasteric Fascia, from the internal oblique muscle. Intercolumnar Fascia, the external spermatic fascia. Superficial Fascia, and the Skin, of the scrotum.

The Vesiculæ Seminales (d, Fig. 126) are two lobulated membranous pouches, which serve as reservoirs for the semen, and secrete a fluid to be added to the secretion of the testicles. They are about 2½ inches long, and are situated externally to the lower ends of the vasa deferentia, between the base of the bladder and the rectum. They are composed of 3 coats,an external areolar, a middle muscular, and an internal mucous coat, lined with columnar epithelium. Their anterior extremities converge toward the base of the prostate gland, where a duct from each joins with the corresponding vas deferens to form-

Ejaculatory Ducts,—one on each side, are formed by the junction of the

vasa deferentia with the ducts of the vesiculæ seminales. They are about  $\frac{3}{4}$  inch in length, and terminate in the prostatic portion of the urethra, by orifices on the sides of the verumontanum.

Arteries,—are derived from the middle and inferior vesical, and the middle hæmorrhoidal; they are accompanied by veins and lymphatics.

Nerves,—are branches from the polvic plexus.

### THE FEMALE ORGANS OF GENERATION.

### THE VULVA.

The Vulva, or Pudendum, are the external genital organs of the female, viz.—the mons Veneris, the labia majora and minora, the clitoris, and the orifice of the vagina. The—

Mons Veneris,—is the rounded eminence in front of the pubic symphysis, formed of fatty tissue beneath the skin, and covered with hair after puberty.

The Labia Majora (1) are two prominent longitudinal folds extending from the mons Veneris to the perinæum. They are formed of hairy integument externally and modified skin internally, between which are areolar and dartoid tissues, fat, vessels, nerves, and glands. They meet in front, forming the anterior commissure (10), and nearly meet behind in the posterior commissure at the anterior boundary of the perinæum. They correspond to the scrotum of the male. The—

Fourchette (2),—is the curved anterior edge of the perinæum, and between it and the hymen (8) there is a depression, the *Jossa navicularis*.

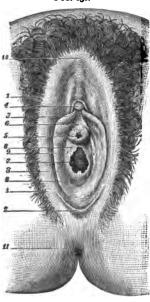

Nerves,—the superficial perineal from the pudic, and the inferior pudendal from the small sciatic.

The Labia Minora (3), or  $Nymph\alpha$ , are two small folds, situated internally to the labia majora, and extending from the prepuce of the clitoris (4) obliquely backward for  $1\frac{1}{2}$  inch on each side of the vaginal orifice, where they are lost on the inner surface of the labia majora. They are composed of modified skin, and have sebaceous follicles on their internal surface.

Clitoris,—is situated beneath the anterior commissure, its glans (4) only appearing externally as a small rounded tubercle between the anterior extremities of the labia minora. It is a diminutive penis, in all but the corpus spongiosum and urethra; having two corpora cavernosa, two crura, a glans, prepuce, suspensory ligament and muscles, the erectores clitoridis.

Vestibule (6),—is a triangular depression in front of the vaginal orifice, bounded laterally by the labia minora.

FIG. 131.

Meatus Urinarius (5),—situated in the vestibule, about an inch below the clitoris, and close to the vaginal orifice.

Bulbi Vestibuli,—are two oblong erectile bodies, situated one on either side of the vestibule, and consisting of a venous plexus surrounded by a fibrous membrane. They are the analogues of the bulb of the corpus spongiosum in the male.

Pars Intermedia,—is a small venous plexus situated between the glans clitoridis and the bulbi vestibuli. It is the analogue of the corpus spongiosum.

Orifice of the Vagina (7),—is surrounded by the sphincter vaginæ muscle, and in the virgin is sometimes partly closed by the hymen.

Hymen (8),—a fold of mucous membrane situated across the lower part of the vaginal orifice, of various shapes, usually a ring, but often semilunar, the concavity upward. It is frequently absent in virgins, and after sexual intercourse

its rupture and cicatrization give rise to small eminences along the margin of the vaginal orifice, named the carunculæ myrtijormes.

Glands of Bartholin,—one on each side of the vaginal orifice, their ducts opening (9) near the inner sides of the labia minora. They are the analogues of Cowper's glands in the male.

Nerves,—to the labia minora as to the labia majora; the bulbi vestibuli and other erectile structures are supplied by filaments from the dorsal nerve of the clitoris, superficial perineal, and hypogastric plexus.

### THE VAGINA.

The Vagina is a curved canal extending from the vulva to the uterus, placed between the bladder in front and the rectum behind. Its length is about 2½ inches along the anterior wall, 3½ inches along the posterior wall,

and its walls are usually in contact with each other. It is very dilatable, especially near its upper end, which surrounds the vaginal portion of the cervix uteri, its attachment extending higher up on the posterior wall of the uterus than on the anterior wall. Its relations are—

Anteriorly,—the urethra and the base of the bladder.

Posteriorly,—the anterior wall of the rectum, and the recto-vaginal fold of peritoneum which forms Douglas' pouch behind its upper fourth.

Laterally,—are attached the levatores ani muscles, and the recto-vesical fascia.

Structure of the Vagina. The vaginal wall consists of a muscular coar externally, a layer of erectile tissue, and a mucous lining covered with squamous epithelium, and furnished with mucous crypts and follicles, but has no glands.

Columns of the Vagina,—are two longitudinal raphés situated along its inner surface, one anteriorly the other posteriorly, which are connected by numerous transverse ridges or rugæ.

Sphincter Vaginæ Muscle,—surrounds the lower end of the vagina; it is described on page 96.

Vessels and Nerves. The Arteries of the vagina are the Vaginal branches of the internal iliac, and branches of the uterine artery, which form in front and behind a longitudinal vessel, the azygos arteries of the vagina. The—

Veins,—are disposed similarly to the arteries, form a rich plexus in the muscular and mucous coats, and terminate in the vaginal and uterine trunks.

Lymphatics,—terminate in the pelvic and inguinal glands.

Nerves,—are derived from the hypogastric plexus, the fourth sacral nerve, and the pudic nerve, forming a vaginal plexus.

### THE UTERUS.

The Uterus is a hollow, pear-shaped, muscular organ, measuring about 3 inches long, 2 inches broad, and 1 inch thick, flattened from before backward, placed base upward, forming an angle with the vagina, which partially receives its cervix, and situated in the pelvic cavity, between the bladder in front and the rectum behind. Its—

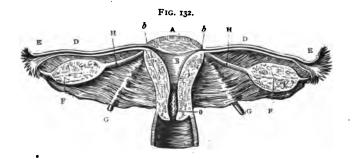

Fundus (A),—is broad, convex, having walls § inch thick, and is covered by peritoneum.

Body,—is about 1\(\frac{1}{2}\) inch long, walls \(\frac{1}{2}\) inch thick, flat anteriorly, convex posteriorly, concave laterally, and joined to the bladder by its lower

anterior fourth. It is invested by peritoneum posteriorly, and in front for its upper three-fourths.

Cervix, or Neck,—is the lower constricted portion, about 13 inch long, walls 14 inch in thickness, and is embraced for 12 to 13 inch by the upper extremity of the vagina.

Cavity of the Body (B),—is small and triangular, flattened from before backward, about 11 inch in length, and has two lateral cornua above,

and a constricted orifice, the os internum, at its lower angle, opening into the cavity of the cervix.

Cavity of the Cervix,—is spindle-shaped, about 13 inch long, and presents on its inner surface transverse folds of mucous membrane proceeding from a longitudinal fold, giving an appearance named the arbor vitæ (o).

Os Uteri,—is a transverse orifice at the lower end of the cervical cavity, opening into the vagina, and having an anterior and a posterior lip.

Ligaments of the Uterus are 8 in number,—1 anterior, 1 posterior, 2 lateral or broad ligaments, 2 sacro-uterine, and 2 round ligaments, all except the last-named being formed of peritoneum. The—

Anterior Ligament, vesico-uterine,—is reflected from the front of the uterus on to the bladder.

Posterior Ligament, recto-uterine,—passes from the posterior wall of the uterus over the upper fourth of the vagina, and thence on to the rectum and sacrum, forming Douglas' pouch behind the upper portion of the vagina.

Lateral or Broad Ligaments 2,—pass from the sides of the uterus to the lateral walls of the pelvis, and form a septum across the pelvic cavity. They contain, between the two folds of peritoneum of which they are composed, the Fallopian tubes, the round ligaments, the ovaries, the

parovaria or organs of Rosenmüller, connective tissue, unstriped muscular fibre, blood-vessels, and nerves.

Sacro-uterine Ligaments 2,—pass from the sides of the uterus to the sides of the rectum, and thence to the sacrum.

Round Ligaments 2 (G),—are two cords, about 4 or 5 inches long, composed of muscular tissue prolonged from the uterus, also areolar and fibrous tissue, vessels and nerves, extending one on each side, from the lateral aspects of the fundus uteri, through the inguinal canals, to the labia majora, where they are lost. Each ligament lies, for a part of its course, between the two layers of the broad ligament, and is covered by a process of peritoneum. The—

Canal of Nuck,—is the extension of the above-named process of peritoneum into the inguinal canal. It exists in the fœtus, and is usually obliterated in the adult.

Structure of the Uterus. The wall of the uterus is composed of 3 coats, an external serous, a middle muscular, and an internal mucous coat. The muscular coat forms the chief bulk of the organ, and consists of bundles of unstriped muscular fibres, disposed in 3 layers interlaced together; circular fibres predominating in the cervix, longitudinal fibres in the body of the uterus. The—

Peritoneal or Serous Coat,—invests the body of the organ, except its lower anterior fourth.

Mucous Coat,—is very thick,  $\frac{1}{12}$  to  $\frac{1}{8}$  inch, and closely adherent to the muscular tissue, having no basement layer of connective tissue. It is covered with ciliated columnar epithelium, and studded with mucous follicles and tubular glands, which are most numerous in the cervix. The follicles, when distended by their own secretions, form sacs, which Naboth mistook for human ova, and hence were named the ovula Nabothi.

Vessels and Nerves. The Arteries of the uterus are the Uterine from the internal iliac, and the Ovarian from the aorta; the two meeting on the side of the body and forming an anastomotic trunk, from which lateral branches are given off to the uterus. They are remarkably tortuous and anastomose freely. The—

Veins,—accompany the arteries, and in the impregnated state become sinuses. They end in the uterine plexuses.

Lymphatics,—those of the cervix end in the pelvic glands, those of the body in the lumbar glands.

Nerves,—are derived from the inferior hypogastric and ovarian plexuses, and from the 3d and 4th sacral nerves.

### APPENDAGES OF THE UTERUS.

The Fallopian Tubes, or *Oviducts* (D), are two tubes, each about 4 inches in length, and  $\frac{1}{16}$  inch in calibre, situated in the free margin of the broad ligament, and extending from the superior angles of the uterus (b) outward, to terminate in free, trumpet-shaped ends. They open by one end into the uterus at its cornua, by the other end into the peritoneal cavity. Their structure is similar to that of the uterus, the mucous lining being continuous with the uterine mucous membrane and with the peritoneum, and lined with ciliated columnar epithelium. Their—

Isthmus,—is the inner constricted third of the tube.

Ampulla,—is the outer dilated portion, curving over the ovary.

Infundibulum,—the trumpet-shaped outer end, with its open mouth, the ostium abdominale, surrounded by—

Fimbria (E),—fringe-like processes, one of which, the fimbria ovarica, is attached to the ovary.

Hydatids of Morgagni (see page 333),—one or more small vesicles ifloating on a long stalk of peritoneum, are frequently found in connecting with or near the fimbriæ.

Vessels and Nerves.—The vessels are those of the ovaries; the nerves are branches from one of the uterine nerves.

The Ovaries (F) are two oval bodies, of grayish-pink color, situated in the broad ligament, behind and below the Fallopian tubes, one on each side of the uterus, to which they are attached by the ligament of the ovary. They each measure about  $1\frac{1}{2}$  inch by  $\frac{3}{4}$  by  $\frac{1}{3}$ , and are invested by peritoneum, except posteriorly. They are composed of a vascular stroma containing the *Graafian vesicles* in various stages of development, and are surrounded by the *tunica albuginea*, a condensed layer of the stroma.

The Graafian Vesicles are the ovisacs containing the human ova, are very numerous (about 70,000 in each ovary), vary in diameter from  $\frac{1}{100}$  to  $\frac{1}{60}$  inch, but after puberty a few are found of from  $\frac{1}{20}$  to  $\frac{1}{6}$  inch or more. Each vesicle has an external fibro-vascular coat, and an internal coat or ovica psule, which is lined by the membrana granulosa, and contains a transparent fluid of albuminous character, containing immature ova. The—

Membrana Granulosa,—is a layer of nucleated cells, lining the ovicapsule; at one point the cells are heaped up in a mass, the discus proligerus, in which the ovum is imbedded.

Corpus Luteum,—is a puckered yellow spot in the substance of the ovary, produced as a result of the rupture of a Graafian vesicle and the discharge of an ovum, probably by the fatty degeneration of the extravasated blood.

Vessels and Nerves. The Arteries are the Ovarian, from the aorta, which also supply the Fallopian tubes, and anastomose with the uterine arteries. The—

Veins,—accompany the arteries, and form a plexus, the pampiniform plexus, near the ovary.

Nerves,—are derived from the inferior hypogastric or pelvic plexus, and from the ovarian plexus.

The Parovarium, or Organ of Rosenmüller, is a group of tubules, situated in the broad ligament, between the ovary and the Fallopian tube, and converging to a large duct, the duct of Gärtner, which ramifies in the broad ligament, descends along the side of the uterus, and terminates in a bulbous enlargement. It is the atrophied remains of the Wolffian Body of feetal life. (See Compend of Physiology, page 260.)

#### THE MAMMÆ.

The Mammæ, or Breasts, are two hemispherical eminences, situated one on each antero-lateral aspect of the chest, extending from the sternum

to the axilla, and from the 3d rib to the 7th. Each breast contains the Mammary Gland and is surmounted by the nipple, around the base of which is a zone of colored cutaneous tissue, the areola, pink in virgins, darker in women who have borne children. In the male the mammæ are rudimentary organs, but capable of development under special circumstances.

Structure of the Mammary Gland. It is a compound conglomerate gland, composed of 15 or 20 lobes and their ducts (1), with a packing of areolar and adipose tissue, enveloped by a fibrous capsule which forms septa between the lobes. Each lobe is made up of lobules (2), and these again are formed by the aggregation of alveoli, terminal vesicles by which the milk is secreted. The—

Tubuli Lactiferi or Tubuli Galactophori(1),—are the excretory ducts of the lobes, one for each. They

FIG. 133.

are formed by the junction of the ducts from each lobule, and converge towards the areola, beneath which they form ampulae or dilatations, and thence, piercing the nipple, open on its summit by separate orifices.

Vessels and Nerves. The Arteries are derived from the thoracic branches of the axillary, the intercostals, and the internal mammary arteries.

Veins,—form the circulus venosus, an anastomotic venous circle around the base of the nipple, from which larger veins run outward, and terminate in the axillary and internal mammary veins.

Lymphatics,—terminate in the axillary glands; a few going to the anterior mediastinal glands.

Nerves,—are derived from the anterior and lateral cutaneous nerves of the thorax.

# HERNIA.

A Hernia is a protrusion of any viscus from its natural cavity. The term, when unqualified as to the viscus, is understood to mean a protrusion of the intestines or mesentery, or both, from the abdominal cavity. Anatomically the most important herniæ are—

Oblique Inguinal Hernia,—in which the protrusion follows the spermatic cord through the inguinal canal; passing to the outer side of the epigastric artery, and through both the internal and external abdominal rings.

Direct Inguinal Hernia,—occurs at Hesselbach's triangle, escaping to the inner side of the epigastric artery, and through the external abdominal ring only.

Femoral Hernia,—in which the protrusion descends through the femoral or crural canal.

### INGUINAL HERNIA.

The Inguinal Canal is a passage in the abdominal wall, parallel to Poupart's ligament, and just above it. It commences at the internal abdominal ring and ends at the external abdominal ring (1), being about 1½ inch in length. It serves for the passage of the spermatic cord in the male, and the round ligament of the uterus in the female; is directed downward and inward, and is bounded as follows:—

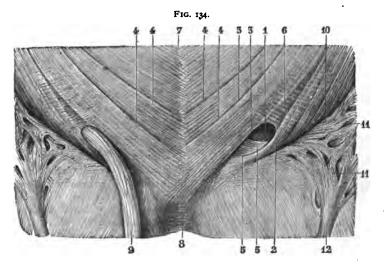

Anteriorly,—the skin, superficial fascia, external oblique muscle, and the internal oblique for the outer third of the canal.

Posteriorly,—the conjoined tendon, transversalis fascia, triangular fascia (5), sub-peritoneal tissue, and peritoneum.

Above,—the arched fibres of the internal oblique and transversalis muscles.

Below,—the union of the transversalis fascia (5) with Poupart's ligament (10).

The Internal or Deep Abdominal Ring,—is an oval opening in the transversalis fascia, formed by the prolongation of this fascia around the cord, as the infundibuliform fascia. It lies ½ inch above Poupart's liga-

ment (10) and midway between the anterior superior spine of the ilium and the spine of the pubes (8). It is bounded above and externally by the arched fibres of the transversalis muscle; below and internally by the epigastric vessels. The—

Epigastric Artery,—lies between the transversalis fascia and the peritoneum, passing obliquely upward and inward along the lower and inner margins of the internal ring.

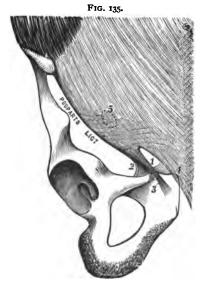

Infundibuliform Fascia,—or infundibuliform process of the transversalis fascia, is a thin, funnel-shaped membrane, arises from the circumference of the internal ring, and is continued around the cord and testis, enclosing them in a distinct pouch.

The External or Superficial Abdominal Ring (1),—is a somewhat triangular opening in the aponeurosis of the external oblique muscle, situated just above and external to the crest of the pubes. It is about 1 inch long, and ½ inch wide, and is bounded laterally by its own margins, called the

external (2) and internal (3) pillars of the ring. It may be easily felt in the living male, by invaginating the skin of the scrotum with the finger, and feeling up along the spermatic cord (9). It is much larger in men than in women. The—

Intercolumnar or External Spermatic Fascia (6),—is formed by tendinous fibres which arch across the lower part of the aponeurosis of the external oblique, between the pillars of the external ring, and are connected together by delicate fibrous tissue. It is continued downward as a tubular prolongation around the cord and testis, enclosing them in a distinct sheath.

Cremasteric Fascia,—passes through the external ring, and consists of a series of muscular loops, united by areolar tissue, forming a thin covering over the spermatic cord and testis. The muscular fibres (Cremaster muscle) are supposed to have been originally part of the internal oblique muscle, carried down by the testicle in its descent to the scrotum. It does not exist in the female.

Poupart's Ligament, or the Crural Arch, is that portion of the aponeurosis of the external oblique muscle which extends from the anterior superior spine of the ilium to the spine of the pubes. Its lower portion (3) forms the external pillar of the external abdominal ring, and its reflection along the pectineal line is called Gimbernat's ligament (2). Other fibres, reflected behind the internal pillar of the ring (4), upward to the linea alba, are termed the triangular jascia (1).

Gimbernat's Ligament (2),—is that portion of the aponeurosis of the external oblique which is reflected upward and outward from the spine of the os pubis to be inserted into the pectineal line. Its

anterior margin is continuous with Poupart's ligament.

Triangular Fascia (1),—is a triangular band, attached by its apex to the

pectineal line, where it is continuous with Gimbernat's ligament; passes inward beneath the spermatic cord, behind the internal pillar of the external ring, and in front of the conjoined tendon, to interlace with its fellow of the opposite side at the linea alba, (see 5, Fig. 134).

Hesselbach's Triangle is a small triangular space on the lower abdominal wall, bounded externally by the deep epigastric artery, internally by the margin of the rectus muscle, below by Poupart's ligament. Its inner 3rds is crossed by the conjoined tendon. Through this space a direct inguinal hernia forces its way. The—

Inguinal Fossæ,—are 3 depressions of peritoneum in the inguinal region above Poupart's ligament. The internal and middle ones lie in Hesselbach's triangle, the external fossa usually corresponds to the internal abdominal ring.

Coverings of Inguinal Hernia depend, in the oblique form, upon the extent to which the hernia descends in or through the inguinal canal. When it has escaped from the external abdominal ring, and is therefore complete, its coverings, from without inward, are 7 in number, as follows:—

- I. Skin.
- 2. Superficial Fascia, -2 layers.
- 3. Intercolumnar Fascia,—from the external abdominal ring.
- 4. Cremasteric Fascia,—from the inguinal canal.
- 5. Infundibuliform Fascia,—from the internal abdominal ring.
- Subserous Areolar Tissue,—almost inappreciable.
- 7. Peritoneum,—the hernial sac proper.

Direct Inguinal Hernia has the same coverings, except that the *Conjoined Tendon* is substituted for the cremasteric fascia, and the *Transversalis Fascia* for the infundibuliform.

### FEMORAL HERNIA.

The Femoral or Crural Canal is a narrow interval,  $\frac{1}{4}$  to  $\frac{1}{2}$  inch long, between the femoral vein (4) and the inner wall of the femoral sheath, extending from Gimbernat's ligament to the saphenous opening. It exists as a distinct canal only when the sheath has been separated from the vein by the pressure of a hernia or tumor, or by dissection. It lies beneath Poupart's ligament (1), is closed above by the septum crurale, below by the cribriform jascia, and is bounded as follows:—

Anteriorly,—by a continuation downward, under Poupart's ligament, of the transversalis fascia, covered by the falciform process of the fascia lata.

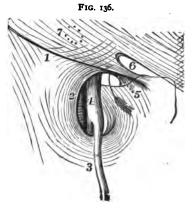

Posteriorly,—by a downward continuation of the iliac fascia, covering the pubic portion of the fascia lata.

Externally,—by the fibrous septum separating it from the inner side of the femoral vein.

Internally,—by the outer edge of Gimbernat's ligament, and the junction of the processes of the transversalis fascia and the iliac fascia, which form the inner side of the femoral sheath.

The Femoral or Crural Ring, the upper opening of the femoral canal, is an oval-shaped opening, about ½ inch in diameter (larger in the female), situated below the internal abdominal ring (7) and Poupart's liga-

ment (1), and between the inner side of the femoral vein and the margin of Gimbernat's ligament (5). It is closed by the septum crurale and a small lymphatic gland. The arrow in the figure points into the femoral ring. The—

Femoral Vein (4),—lies next on its outer side.

Deep Epigastric Artery,—crosses its upper and outer angle.

Obturator Artery,—when arising from a common trunk with the epigastric, as it does once in 3½ subjects, may lie close along its internal and superior margins.

Communicating Branch,—between the deep epigastric and obturator arteries, lies in front of the ring.

Spermatic Cord,—in the male, lies directly above its anterior margin, replaced by the round ligament in the female.

Septum Crurale, or Fascia of Cloquet,—is a layer of condensed areolar tissue, supporting a lymphatic gland, and perforated for the passage of lymphatic vessels. It lies across the femoral ring, and forms one of the coverings to any hernia escaping thereby.

The Saphenous Opening, the lower orifice of the femoral canal, is an oval-shaped aperture,  $1\frac{1}{2}$  by  $\frac{1}{2}$  inch in diameter, formed by a reflection of the fascia lata inward around and under the end of the internal saphenous vein (3). It is situated below the inner third of Poupart's ligament, and is covered by the *cribriform fascia*. Its inner margin curves upward behind

the saphenous vein and under the outer margin, and is blended with the pubic portion of the fascia lata over the pectineus muscle. Its outer margin curves over the inner to the spine of the pubes, as a—

Falciform Process, or Superior Cornu,—is thin but strong, sharply defined, and lies on a plane anterior to the inner margin. It ascends in front of the femoral vessels, and curving inward is attached to Poupart's ligament, the spine of the os pubis, and the pectineal line, where it is continuous with the pubic portion. It is sometimes named the ligament of Burns, its pubic end is called the ligament of Hey.

Cribriform Fascia (11, Fig. 134),—is the portion of the deep layer of the superficial fascia which covers the saphenous opening. It is perforated by the internal saphenous vein and by numerous blood-vessels and lymphatics.

The Femoral or Crural Sheath, the investing sheath of the femoral vessels, is a funnel-shaped prolongation of the lining fasciæ of the abdomen, the transversalis fascia in front, and the iliac fascia behind. The sheath is divided by two septa into 3 compartments, the external of which contains the *femoral artery*, the middle one the *femoral vein*, the internal one being the *femoral canal*. The sheath is perforated anteriorly by the genito-crural nerve, internally by the internal saphenous vein, and forms one of the coverings of a femoral hernia. The—

Deep Crural Arch,—is the thickened border of the transversalis fascia, which arches across the front of the crural sheath, and is intimately connected to it. Externally it is attached to the centre of Poupart's ligament, internally it is inserted into the pectineal line behind the conjoined tendon.

Coverings of Femoral Hernia depend upon whether the hernia has or has not escaped from the saphenous opening, and is therefore complete or incomplete. In the latter case, the covering, from without inward would be—skin, superficial fascia, falciform process of the fascia lata, crural sheath, septum crurale, subserous areolar tissue (fascia propria), and peritoneum The coverings of a complete femoral hernia are as follows:—

- 1. Skin.
- 2. Superficial Fascia,—its superficial layer.
- 3. Cribriform Fascia,—from the saphenous opening.
- 4. Crural Sheath,—from the transversalis fascia.
- 5. Septum Crurale,—from the femoral ring.
- 6. Subserous Areolar Tissue,—the fascia propria of Cooper.
- 7. Peritoneum,—the proper hernial sac.

# THE PERINÆUM.

The Perinæum is a triangular space containing the structures which close the inferior outlet of the pelvic cavity anterior to a line drawn between the tuberosities of the ischia. Posteriorly to this line the corresponding space is named the *Ischio-rectal Region*. The Perinæum is bounded laterally by the rami of the pubes and ischia, anteriorly by the symphysis pubis, and posteriorly by the line above mentioned, which averages about 2½ inches in length.

For the Muscles of the Perinæum, see page 05.

## THE PELVIC CAVITY.

The Pelvic Cavity is that portion of the abdominal cavity which lies below the level of the ilio-pectineal line and the promontory of the sacrum. The osseous pelvis is described on page 17. The boundaries of the pelvic cavity are as follows:—

Anteriorly and Laterally,—the pubes and ischia, covered by the obturator muscles.

Posteriorly,—the sacrum and coccyx, the pyriformis muscles, and the great sacro-sciatic ligaments.

Floor,—is formed by the recto-vesical fascia, covering the levator ani and coccygeus muscles of each side, and the triangular ligament of the urethra.

Contents of the Pelvic Cavity are the bladder, rectum, some convolutions of the small intestine, and some of the organs of generation. They are partially covered by peritoneum, and supplied with vessels and nerves.

### THE PELVIC FASCIA.

The Pelvic Fascia lines the pelvic cavity and is continuous with the iliac fascia above. At the level of a line drawn from the back of the symphysis pubis to the spine of the ischium, it is thickened into a white line or band, where it gives origin to the levator ani muscle, and divides into 2 layers, the recto-vesical fascia or visceral layer, and the obturator fascia or parietal layer. The—

Recto-vesical Fascia, visceral layer of the pelvic fascia,—descends from the white line over the upper or pelvic surface of the levator ani muscle, and is prolonged over the prostate gland, rectum, vesiculæ seminales, and the bladder, forming the lateral true ligaments of the latter organ.

Obturator Fascia, the parietal layer of the pelvic fascia,—descends from

the white line along the wall of the pelvis, and covers the obturator internus muscle, near the lower border of which it forms a canal between its layers, Alcock's canal, for the pudic vessels and nerve. Above this canal it gives off a thin membrane, the ischio-rectal or anal-jascia over the lower or perineal surface of the levator ani muscle; also a process, which with its fellow of the opposite side forms the deep layer of the triangular ligament.

Illustration of the Pelvic Fascia. The capital letter K, having a horizontal arm added to it, thus K, will illustrate the pelvic fascia of the right side, seen from the front in vertical section. The vertical line of the K represents the pelvic fascia above, the obturator fascia below. The upper arm represents the lateral ligament of the bladder, the horizontal arm the recto-vesical fascia, and the lower arm the ischio-rectal fascia. The space between the lower arm and the vertical line represents the ischio-rectal fossa.

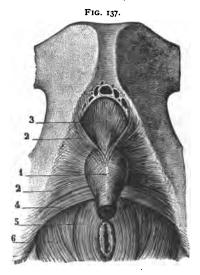

# THE MALE PERINÆUM.

The Male Perinæum, in the adult, varies in breadth on the base line,

from 2 to 3½ inches, the average being 2¾ inches. Its middle line is convex, corresponds to the bulb of the urethra, and presents a prominent raphé, which is continuous in front with the raphé of the scrotum. Its muscles are described on page 95; but two slips have received special names, as follows:—

Muscle of Guthrie, Transversus Perinæi Profundus,—is the lowermost part of the inferior fasciculus of the compressor urethræ muscle (2), behind the bulb (1), and in front of the transversus perinæi (4).

Muscle of Wilson (3),—is a fasciculus which descends vertically from the body of the

pubis to unite with the superior fasciculus of the compressor urethræ (2). The above-named muscles are situated in front of the sphincter ani (5)

and the levator ani (6), and on a plane superficial to that of the latter muscles.

Fasciæ of the Perinæum are superficial and deep, each consisting of two layers; the deep fascia being usually called the triangular ligament of the urethra. The—

Superficial Layer of the Superficial Fascia,—is thick, loaded with fat, and continuous with the subcutaneous fascia of the thighs.

Deep Layer of the Superficial Fascia, Colles' Fascia,—is thin but strong, continuous in front with the dartos of the scrotum, and attached on each side to the rami of the pubes and ischium; posteriorly it joins the deep perinæal fascia under the transversus perinæi muscle. It sends inward a vertical septum which is incomplete in front. [This fascia was called by Professor Pancoast the "anterior leaflet of the triangular ligament."]

Anterior Layer of the Deep Perinæal Fascia,—is triangular in shape, and extends from the pubic arch and the sub-pubic ligament, laterally to the rami of the pubes and ischia, and posteriorly to the central tendinous portion of the perinæum, where it becomes blended with the deep layer of the superficial fascia. It embraces the anterior part of the membranous portion of the urethra. [Called by Professor Pancoast, the "middle leaflet of the triangular ligament."]

Posterior Layer of the Deep Perinæal Fascia,—has the same attachments as the anterior layer above described, but in its course it embraces the posterior part of the membranous portion of the urethra, and is in connection with the apex of the prostate gland. [Called by Prof. Pancoast, the "posterior leaflet of the triangular ligament."]

Buck's Fascia is a continuation of the deep layer of the superficial fascia of the perinæum, extending forward upon the penis, which it invests completely as far as the glans. It is continuous above with the suspensory ligament of the penis, and is held by some anatomists to prove that the deep layer aforesaid is not continuous in front with the dartos of the scrotum. This fascia was named from Dr. Buck, an American surgeon, who, in 1846, first insisted on the importance of this structure. It modifies the direction of urinary infiltration of the perinæum, until perforated.

The Triangular Ligament of the Urethra according to some authorities is the anterior layer of the deep perinæal fascia, according to others it includes the posterior layer also. Prof. Pancoast included in the term Triangular Ligament all three layers which are united at the central tendinous portion of the perinæum, including therefore the deep layer of the superficial

perinæal fascia. As usually described, it includes both layers of the deep perinæal fascia, (see above); and is in relation with the following-named structures:

Superficially to it, but behind the deep layer of the superficial fascia, the

Crura of the Penis (4). Erector Penis Muscle (10).

Corpus Spongiosum. Transversus Perinæi Muscle (14).

Bulb of the Urethra. Transversus Perinæi Artery.

Accelerator Urinæ Muscle (8). Superficial Perinæal Vessels (5).

Central Tendinous Point of the Perinaum.

Between its layers, in the so-called cavity of the triangular ligament, the

Membranous Urethra. Dorsal Vein of the Penis.

Compressor Urethræ Muscle. Artery of the Bulb.

Pudic Vessels and Nerve (11). Nerve of the Bulb.
Cowber's Glands and Ducts. Plexus of Veins.

Cowper's Glands and Ducts. Plexus

Behind its superior (deep) layer, are the—

Bladder. Rectum.

Prostate Gland. Levator Ani Muscle (18).

Central Tendinous Point is a fibrous point in the middle line of the perinæum, internal to the deep layer of the superficial fascia and about ½ inch in front of the anus. It corresponds to the centre of the lower margin or base of the triangular ligament (12), and is the point of attachment for 4 converging muscles, the—external sphincter (16), accelerator urinæ (8), and two transverse perinæal (14).

### ISCHIO-RECTAL REGION.

The Ischio-rectal Region is the triangular space behind the perinæum, extending posteriorly to the tip of the coccyx, and laterally to the tuberosities and rami of the ischia. In the middle line it presents the anal orifice, and deeply on each side, the Ischio-rectal Fossa, which contains the lower part of the rectum, areolar tissue and fat. The fossa is about 1 inch broad at its base and about 2 inches deep; its apex, directed upward, corresponds to the junction of the obturator fascia and the ischio-rectal fascia. It contains the—

Superficial Fascia,—is thick, areolar in texture, with much fat in its meshes, also branches of the perforating cutaneous nerve.

Muscles,—the corrugator cutis ani, external and internal sphincters (16), and the levator ani (18).

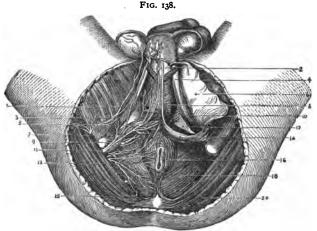

Rectum,—surrounded by areolar tissue and fat.

Internal Pudic Artery (11),—with its veins and the two divisions of the nerve, about ½ inch above the margin of the tuberosity of the ischium.

Inferior Hemorrhoidal Vessels and Nerves (13),—cross the space transversely.

Superficial Perinaal Vessels (5) and Nerves (3),—in the front part of the space for a short distance.

Branch of the 4th Sacral Nerve,—at the back of the space, near the coccyx.

Ischio-rectal or Anal Fascia,—a thin membrane given off from the obturator fascia over the levator ani muscle, at the apex of the fossa, (see page 351).

Obturator Fascia,—covering the obturator internus muscle, at the outer side of the fossa, (see page 350).

Recto-vesical Fascia, -invests the internal surface of the levator ani muscle, near the base of the fossa; also the rectum at the inner side of the fossa, (see page 350).

### LITHOTOMY.

Structures Divided in Lithotomy. In the Lateral Operation the knife is inserted deeply 11 inch in front of the anus, a little to the left of the median line, and the incision is carried obliquely backward and outward, becoming more superficial as it is extended, to a point midway between the anus and the tuberosity of the left ischium, dividing the-

Skin and Superficial Fascia (first layer of the latter).

Inferior Hemorrhoidal Vessels and Nerves (13).

Deep Layer of the Superficial Fascia (6).

Superficial Perinæal Vessels (5) and Nerves (3).

Accelerator Urinæ Muscle (8) (posterior fibres).

Transversus Perinæi Muscle (14) and Artery.

Inferior Layer of the Triangular Ligament (12).

Compressor Urethræ Muscle (a few fibres).

Levator Ani Muscle (18) (anterior fibres).

Membranous and Prostatic Portions of the Urethra (2).

Superior Layer of the Triangular Ligament (12).

Prostate Gland, (part of the left lobe).

Neck of the Bladder, (in part).

In Median Lithotomy, the incision, 1½ inch long, is made transversely through the central tendinous point and raphé, dividing the—

Skin and Superficial Fascia.

Sphincter Ani Muscle (16) (some of its anterior fibres).

Branches of the Transverse Perinæal Vessels and Nerves.

Base of the Triangular Ligament (12).

Membranous Portion of the Urethra (2).

Compressor Urethræ Muscle.

Structures to be Avoided in Lithotomy. In the Lateral Operation the structures to be remembered and avoided in making the incision are the—

Bulb, its Artery, and the Rectum,—inwardly and in front; avoided by not making the primary incision too near the middle line nor too far forward.

Pudic Artery (11),—externally; avoided by not carrying the incision too far outwardly.

Prostate Gland and Veins,—behind; avoided by not carrying the deep incision too far backward, so as to cut through the entire lobe of the prostate gland, permitting the urine to infiltrate into the loose areolar tissue around the rectum, instead of escaping externally.

# THE FEMALE PERINÆUM.

The Female Perinæum performs the special function of supporting the posterior wall of the vagina, and thereby aiding materially in the support of the whole vagina, the uterus and the bladder. The—

Perinæal Body,—is the pyramidal-shaped prolongation of the female perinæum upward between the vagina and the rectum. It measures about 1½ inch antero-posteriorly, and extends laterally from one ischial tuber-

osity to the other. In it are situated the muscles of the external organs of generation.

Differences between the Female and Male Perinæa are chiefly due to the perforation of the structures in the median line of the female perinæum by the vulvo-vaginal passage. The—

Superficial Fascia,—is incomplete, by reason of its perforation by the orifice of the vulva, but consists of two layers, as in the male.

Deep Perinaal Fascia,—being also perforated by the vagina is less apparent than in the male, though presenting two layers, with the urethra perforating them, as in the other sex.

Bulbi Vestibuli and Partes Intermediales,—represent the corpus spongiosum of the male, divided into two lateral segments.

Prostate Gland,—is absent in the female, but its place is occupied by a number of minute glands disposed around the neck of the bladder.

Muscles,—the Sphincter Vaginæ in the female, takes the place of the accelerator urinæ in the male; the Transversus Perinæi is similar in both sexes; the Erector Clitoridis is smaller than the erector penis, but differs in no other respect; the Compressores Urethræ are separate and attenuated in the female, their anterior fibres passing in front of the urethra, the middle fibres to the sides of the vagina, the posterior fibres to the central tendinous point of the perinæum.

# INDEX.

Note.—Titles which contain the name of a person are entered twice, one entry being under the person's name, the other under that of the structure.

# A POCKET CYCLOPEDIA OF MEDICINE and SURGERY

EDITED BY

# GEORGE M. GOVLD, A.M., M.D.

Author of "Gould's Medical Dictionaries;" Editor of "American Medicine"

# WALTER L. PYLE, A.M., M.D.

Amistant Surgeon Wills Eye Hospital, Philadelphia; formerly Editor
"International Medical Magazine," etc.

BEING BASED UPON GOULD AND PYLE'S LARGE "CYCLOPEDIA OF PRACTICAL MEDICINE AND SURGERY"

Vniform with Gould's Pocket Dictionary. 64mo. Flexible Leather, Gilt Edges, Round Corners, net \$1.00; with Thumb Index, \$1.25

HIS book bears to Gould and Pyle's large "Cyclopedia of Medicine and Surgery" a relation similar to that which the Pocket Dictionary bears to Gould's complete "Illustrated Dictionary." As the Dictionary gives the derivation, pronunciation, and definition of medical words, the Cyclopedia is designed to furnish general

information concerning medical subjects. Every subject, concerning which the student may desire a brief and thorough description, supplementing the mention which may be given in lectures or a general text-book, is taken up and treated thoroughly and concisely. To those desiring concise authoritative information on medical or surgical themes or who wish to look up any new term or matter of recent discovery and use, the book will prove invaluable. It includes articles on Emergencies, Hygiene, Poisons, Nursing, etc.; describes Drugs and their Uses; gives Treatment of Diseases; explains Surgical Operations; contains many Prescriptions and Formulæ, Tables of Differential Diagnosis, Dose Table in both English and Metric Systems, etc.
